 ADDITIONAL INFORMATION ON NIPPON MAX FILTERS	 70

The information in this catalogue has been compiled with every care and to the best of our knowledge at the time of publication. This catalogue is effective from January 2001 and supersedes all previous catalogues. NAP (a division of J. H. McLoughlin Ltd.) cannot accept responsibility for any inaccuracies which may be contained within. No part of this listing may be reproduced without permission of NAP. Nippon Max & Max Filters are registered European trademarks of J. H. McLoughlin Ltd.

APPLICATION LIST AND CROSS REFERENCE GUIDE

Application list and cross references are for guidance only and should not be used to determine the correct filter for any vehicle. We recommend that the fitter make the final judgement. Original part numbers of vehicle manufacturers are provided for comparison purposes only.

Nippon Max Filters are manufactured to the highest Filtration performance standards demanded by todays Engine and Car manufacturers. We have enclosed below some additional and helpful information which you should consult when fitting a Nippon Max Filter.

AN OIL FILTER'S JOB.

In addition to motor oil, every car needs an oil filter to help keep it running. While motor oil lubricates the engine, the oil filter stops the solid deposits from reaching critical engine parts.

These deposits can result in dangerous levels of engine wear. We all know that as oil passes through the engine, it lubricates such parts as the valves, cylinder walls and pistons, camshafts and connecting rod and crankshaft bearings. As the oil flows over these various parts, it picks up small metal particles, dirt and other types of harmful grit. A good motor oil chemically holds these harmful deposits in suspension until it reaches the filter, where the deposits are trapped and removed from the circulating motor oil.

Even though the oil pump pickup tube has a screen that removes large particles, the oil filter is still responsible for most of the filtering. Nippon Max Filter media is designed to trap the most harmful particles—those between 10 and 20 microns—the first time they reach the filter. Wear particles in the 10 to 20 micron size range can be forced through the oil passages of your engine. These dirt particles can rip and gouge bearing and cylinder surfaces.

Test results have shown that particles under 20 microns in size cause far more engine wear than larger size particles. Generally, particles less than 10 microns remain suspended in the oil so wear surfaces in the engine are protected. Large particles (over 20 microns) will not fit in tight engine spaces. They usually remain lodged in crevices, until oil pressure breaks them up into smaller particles. Therefore, a filter that traps and holds more particles in the 10 to 20 micron size offers better engine wear protection.

The contamination in the oil that the filter must remove is produced both inside and outside the engine. Internal contamination is caused by tiny metal particles that normally wear off the moving parts of the engine. External contamination is due to the abrasive dust and dirt in the air that enters through the air intake system, as well as the fuel system and its by-products. Nippon Max Oil filters can handle both kinds of contaminants.

HOW OFTEN SHOULD YOUR OIL FILTERS BE REPLACED?

Oil Filters should be changed every time the oil in the car is changed. Oil passes through your engine four times for every mile you drive. By the time you drive 3,000 miles, the same oil has passed through your filter 12,000 times.

Consult the owner's manual for recommended maintenance intervals. To provide greater protection against engine wear, most experts suggest changing your customers' oil every three months or 3,000 miles (2,500 miles with turbo-charged designs and stop-and-go driving styles). A used oil filter contains dirty oil and contaminants, and if the oil is changed but the filter isn't, that dirty oil in the filter quickly adds its load of contaminants to the fresh oil. It's like pouring fresh milk into a dirty glass.

N.B. By performing preventive maintenance such as changing the oil and filter, a vehicle's engine life can be extended

WHAT CAUSES OVER-PRESSURIZATION?

Over-pressurized Filters. From time to time, a used oil filter will appear bulged or deformed. A bulged oil filter is one that has been subjected to too much pressure — a condition that occurs when the oil pressure regulating valve is malfunctioning. When a bulged oil filter is discovered, the pressure regulating valve should be serviced immediately.

What causes over-pressurization? Excessive engine oil pressure is the result of a faulty oil pressure regulating valve. To properly separate the engine parts and prevent excessive wear, the oil must be under pressure. The pump supplies oil at volumes and pressures greater than what the system requires to lubricate the bearings and other moving parts. The regulating valve opens to allow excess volume and pressure to be diverted.

There are two ways that the valve fails to operate correctly: either it sticks in the closed position, or it is slow to move to the open position after the engine has started. **Unfortunately, a stuck valve can free itself after filter failure, leaving no evidence of any malfunction.**

Note: Excessive oil pressure will cause filter deformation. If the regulating valve still remains stuck, the gasket between the filter and the base can blow out or the filter seam will open. The system will then lose all of its oil. Engine oil over-pressurization is a fault of the engine not the oil filter. To minimize the risk of an over-pressurized system, motorists should be advised to: **Change the oil and filter often.**

WHAT VALVES ARE IN OIL SYSTEMS AND ARE THEY IN THE OIL FILTER?

Oil Pressure Regulating Valve. The oil pump pressure regulating valve, usually built into the oil pump, helps control the operating pressure of the lubrication system. The regulating valve is set by the manufacturer to maintain the correct pressure. The valve utilized a ball (or plunger) and spring mechanism. When the operating pressure is below the preset PSI level, the spring holds the ball in the closed position so that oil flows to the bearings under pressure. When the desired amount of pressure is reached, the valve opens enough to maintain this pressure. Once the valve is open, the pressure remains fairly constant, with only small changes as the engine speed varies. If the oil pressure regulating valve becomes stuck in the closed position or slow to move to the open position after the engine has started, the pressure in the system will exceed the regulating valve setting. This may cause an over-pressurized oil filter. If a deformed oil filter is observed, the oil pressure regulating valve must be serviced immediately.

Relief (By-Pass) Valve. In a full flow system, all the oil passes through the filter to reach the engine. If the filter clogs, an alternative route to the engine must be provided for the oil, or the bearings and other internal parts may fail, due to oil starvation. A relief, or by-pass, valve is used to allow unfiltered oil to lubricate the engine. Unfiltered oil is far better than no oil at all. This relief (by-pass) valve is built into the engine block in some cars. Otherwise, the relief (by-pass) valve is a component of the oil filter itself. Under normal conditions, the valve remains closed. When there is sufficient contaminant in the oil filter to reach a preset level of pressure differential to oil flow (around 10-12 PSI in most passenger cars), pressure differential on the relief (by-pass) valve caused it to open. This condition can occur

when the oil filter has become clogged or when the weather is cold and the oil is thick and flows slowly.

Anti-Drainback Valve. Some oil filter mountings may allow oil to drain out of the filter through the oil pump when the engine is stopped. When the engine is next started, oil must refill the filter before full oil pressure reaches the engine. The anti-drainback valve, included in the filter when required, prevents oil from draining out of the filter. This anti-drainback valve is actually a rubber flap that covers the inside of the inlet holes of the filter. When the oil pump starts pumping oil, the pressure will unseat the flap. The purpose of this valve is to keep the oil filter filled at all times, so when the engine is started there will be an almost instantaneous supply of oil to the engine.

Anti-Siphon Valve. When a turbocharged engine is turned off, it is possible for the turbocharger's lubrication circuit to siphon oil from the oil filter. To prevent this from happening, the turbocharged engine's oil filter is equipped with a specially designed, one-way, shut-off called the anti-siphon valve. Oil pressure keeps this spring-loaded valve open while the engine is turned on. When the engine is turned off and oil pressure drops to zero, the anti-siphon valve automatically closes to prevent the back-flow of oil. This valve insures that there will be a continuous supply of oil available to the turbocharger and the engine's lubrication system upon start-up.

Note On Dry Starts: If a vehicle has not been operated for several days or after oil and filter change, some oil may have drained from the filter in spite of the special valves. This is why it is always a good idea to start the engine slowly, letting it run on idle for 30-60 seconds so the lubrication system will be fully charged with oil before a heavy load is placed on the engine.

INSTALLATION

To install your oil filter:

A spin-on filter is perhaps the most commonly replaced service part on your car or light truck. Timely, proper installation can help prevent internal damage and oil filter leakage. Most filters have instructions printed on them. Follow these five steps when changing any spin-on oil filter: Before commencing you should ensure that the new filter is the correct filter for your car. Check that the number on the filter corresponds with the number in the owners handbook and in this manual. Check that the size of the filter is reasonable compared with the one that you are removing.

Step One: Warm up your vehicle to normal operating temperature to remove contaminants from engine. Stop engine. Secure vehicle (emergency brake, wheel blocks, ramps, etc.) to protect accidental rolling and to provide easy access to the oil filter.

Step Two: Slide drain pan under drain plug. Loosen drain plug by turning it in a counterclockwise direction with a wrench or socket (see Figure 1). Remove drain plug by hand, keeping inward

pressure on the plug to avoid burning yourself with hot oil. Allow oil to completely drain from engine. Clean drain plug and drain hole. Replace drain plug (finger-tighten to ensure correct threading, then finish with wrench or socket).

Step Three: Place drain pan under filter. Remove filter by turning it in a counter-clockwise direction (see Figure 2) with oil filter wrench. Be careful! Filter and oil will be hot. Clean filter mounting base (see Figure 3), removing previous filter gasket if it's still attached to the base.

Step Four: Make sure gasket on new filter is securely in place. Rub a thin film of clean motor oil over entire gasket surface (see Figure 4). Spin filter onto filter mounting base, making sure gasket makes contact. Tighten filter by hand only, following filter's installation instructions.

Step Five: Remove oil cap on valve cover. Refill crankcase with recommended type, weight and amount of new motor oil (see Figure 5). Replace oil cap. Start engine and check immediately around filter and drain plug for leakage. If there are no leaks present then leave motor running for 10 minutes and continue to observe. Properly dispose of used oil and filter.

WHY CHANGE YOUR AIR FILTER?

The air filter and positive crankcase ventilation (PCV) valve are important parts of your vehicle's fuel system. The air filter provides clean air to a vehicle's carburation system, and if it becomes clogged or dirty, it can cause your car to idle or run roughly and reduce gas mileage. The PCV valve helps prevent the release of gas fumes from the engine. If it becomes blocked or clogged, it can cause oil leaks and promote the formation of sludge in the engine. You should check your air filter every six months and replace it according to the vehicle manufacturer's recommendations. If you're unsure, replace the filter every 12 months or 12,000 miles, or sooner if the vehicle is operated in extremely dusty conditions. Replace the filter when it appears dirty or clogged. Replace the crankcase breather filter at the same time if it's dirty. Check the PCV valve and any related hoses whenever you check or replace the air filter. It's also a good idea to check the fuel filter, spark plugs, points, condenser, cap, rotor and wires.

To change your air filter you will need: Pliers, Screwdrivers, Assorted Wrenches.

TO INSTALL YOUR AIR FILTER:

These instructions will help you replace paper-type carburettor air filters and air cleaner-mounted crankcase breather filters. READ these instructions completely before you begin:

Old Air Filter Removal: Raise the hood and find the air cleaner assembly. It's the round can located on top of the carburettor. Remove the wing nut on top of the can, or remove the retaining clips located around the edge of the can. Lift off the top pan and set it aside. You probably won't have to disconnect any hoses, but, if you do, make sure to label and reattach them in their original positions. If necessary, make a drawing to help you. Remove the old air filter cartridge and dispose of it properly.

Check Crankcase Breather Filter: The crankcase breather filter is usually located around the edge of the air cleaner can. Remove the filter. Sometimes it will simply lift out, but some breather filters are held in place by a clip. Remove the clip (and the hose, if necessary) and the filter will come out. Inspect the filter. If it's dirty, dispose of it properly. Wipe the inside of the air cleaner can with a clean rag. If necessary, replace the crankcase breather filter (and the clip and hose, if removed).

New Air Filter Installation: Drop the new filter into place in the air cleaner can. Replace the lid and finger-tighten the wing nut so it's snug or snap the retaining clips around the edge of the can back into place. Make sure any hoses you remove are replaced in their original positions.

Replacing the PCV Valve: The PCV valve is usually located at the end of a hose running from the air cleaner to the engine valve cover. Likely locations of the valve (see diagram 5) are in the valve cover (1-2), at the carburettor (3) or in the intake manifold (4). Diesel engines do not have a PCV valve. Pull the valve from the grommet. A PCV valve that is functioning properly will usually rattle when shaken. If the valve is held in place with a hose clamp, squeeze the hose clamp apart with pliers. Remove the valve from the end of the hose. Check to be sure that the hose is not clogged or brittle. If it is, it should be replaced. Insert a new PCV valve into the end of the hose. Reinstall the hose clamp (if present). Push the PCV valve back into the grommet. Be sure the other end of the hose is properly connected.
