DIAGNOSTIC CODE INDEX

DIAGNOSTIC CODE INDEX

DTC	Description
B1810	DRIVER DOOR AJAR INPUT CIRCUIT LOW
B1811	DRIVER DOOR AJAR INPUT CIRCUIT HIGH
B1BE3	DRIVER PRESENCE DETECTION SENSOR PERFORMANCE
B1BE7	DRIVER PRESENCE DETECTION SENSOR CIRCUIT LOW
B1BE9	DRIVER PRESENCE DETECTION SENSOR CIRCUIT HIGH
B23BB	STOP/START DISABLE SWITCH 1 CIRCUIT OPEN
B23BC	STOP/START DISABLE SWITCH 1 CIRCUIT PERFORMANCE
B23BD	STOP/START DISABLE SWITCH 1 CIRCUIT LOW
B23BE	STOP/START DISABLE SWITCH 1 CIRCUIT HIGH
B23BF	STOP/START DISABLE SWITCH 2 CIRCUIT OPEN
B23C0	STOP/START DISABLE SWITCH 2 CIRCUIT PERFORMANCE
B23C1	STOP/START DISABLE SWITCH 2 CIRCUIT LOW
B23C2	STOP/START DISABLE SWITCH 2 CIRCUIT HIGH
B23C3	STOP/START DISABLE SWITCH 1/2 CORRELATION
B25BC	LEFT FRONT DOOR AJAR SWITCH STUCK CLOSED
B25C7	DRIVER DOOR AJAR SWITCH 2 CIRCUIT LOW
B25C8	DRIVER DOOR AJAR SWITCH 2 CIRCUIT HIGH
B25C9	DRIVER DOOR AJAR SWITCH 2 STUCK CLOSED
B25CB	DRIVER DOOR AJAR SWITCH 1/DRIVER DOOR AJAR SWITCH 2 CORRELATION
C0062	LONGITUDINAL ACCELERATION SENSOR
C0501	WHEEL SPEED SIGNAL LEFT FRONT RATIONALITY
C0507	WHEEL SPEED SIGNAL RIGHT FRONT RATIONALITY
C050D	WHEEL SPEED SIGNAL LEFT REAR RATIONALITY
C0513	WHEEL SPEED SIGNAL RIGHT REAR RATIONALITY
C053D	BRAKE PRESSURE SENSOR 1 PERFORMANCE
C0572	MASTER CYLINDER PRESSURE SENSOR CIRCUIT HIGH
C10F5	BRAKE TORQUE PERFORMANCE
P000A	BANK 1 CAMSHAFT 1 POSITION SLOW RESPONSE
P000B	BANK 1 CAMSHAFT 2 POSITION SLOW RESPONSE
P000C	BANK 2 CAMSHAFT 1 POSITION SLOW RESPONSE
P000D	BANK 2 CAMSHAFT 2 POSITION SLOW RESPONSE

DIAGNOSIS AND TESTING

B1810-DRIVER DOOR AJAR INPUT CIRCUIT LOW

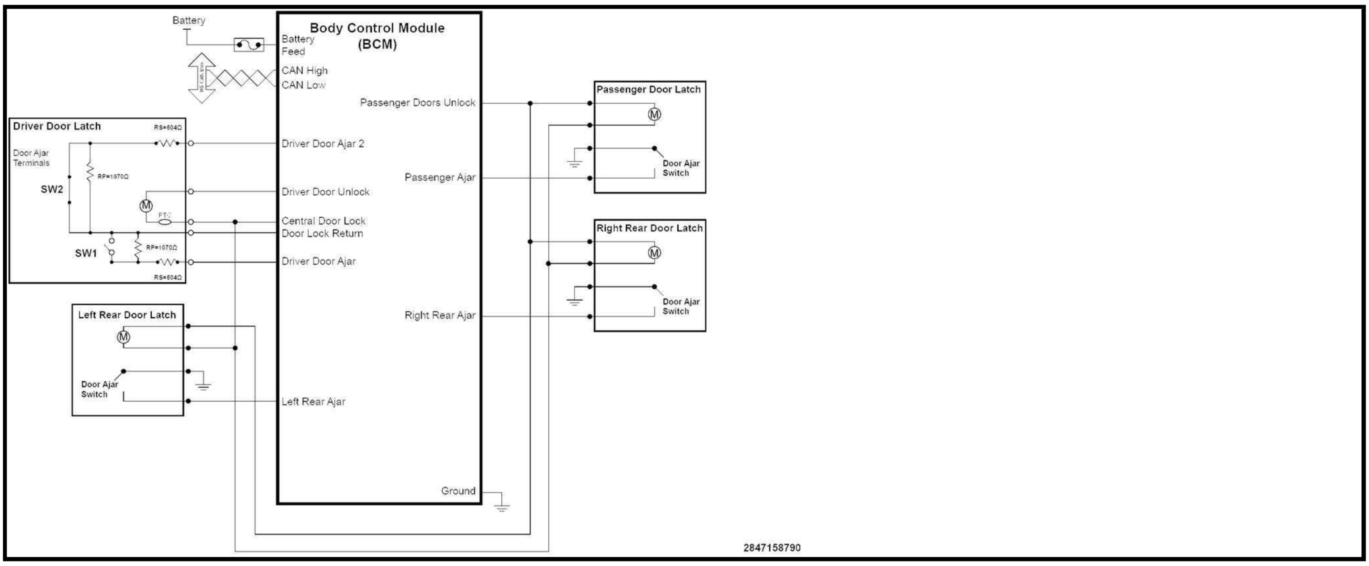
For a complete DOORS/LOCK SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Powertrain Control Module (PCM) receives the state (open/closed) of each switch over the CAN Bus from the Drivers Door Module (DDM) or Body Control Module (BCM) depending on the vehicles configuration and which module the latches are hard-wired to. The PCM continuously monitors the functioning status of the Driver Door Ajar Switch states for the operation of certain features such as Electric Stop/Start (ESS).

For further information on the effect of this DTC to the operation of ESS, see **ENGINE START/STOP (ESS) INOPERATIVE.** . Refer to ENGINE STOP/START (ESS) SYSTEM INOPERATIVE .

COMPONENT FUNCTIONAL DESCRIPTION - DOOR LATCH SYSTEM



Functional Operation of the Lock Motors: The Body Control Module (BCM) uses an H-Bridge configuration to drive the lock/unlock motors. To lock the doors, voltage is applied to the Lock pin circuit and ground is applied to both Unlock pin circuits. To unlock the doors, voltage is applied to the Unlock pins and ground is applied to the Lock pin. The passenger doors have a separate Unlock pin so that only the Driver's Door can be unlocked with the first button press on the keyless remote. When the lock motors are activated BCM will drive the motors for approximately 370 ms. The BCM and lock motors operate in the voltage range of 9.0 and 16.0 volts. Typical current draw for the motors are listed in Amps in the table below.

NOTE: **The amperage values listed in the table are approximate.**

BATTERY VOLTAGE	IN-RUSH CURRENT	CONTINUOUS OPERATION (NO LOAD)	STALL CURRENT
9.0	3.9	3.1	4.3
12.0	5.22	1.75	6.2
13.5	5.8	1.5	6.9
16.0	6.7	2.0	7.0

Functional Operation of the Latch Switches: All of the Door Latches are monitored to determine if they are closed or ajar. All of the ajar switches are wake-up signals to the BCM. The Driver Door Latch must be rationalized in order for some vehicle features to function. Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Door Ajar Switch signals use Battery voltage for a reference. The switches operate in the following manner:

- **Driver Door Ajar Switches:** The BCM has an internal pull up 1000 Ohm resistor for each ajar signal. Each switch has an internal 604 Ohm and 1070 Ohm resistor. When the switches are open the resistance through the switches are 1674 Ohms. When the switches are closed the resistance through the switches are 604 Ohms. The switch states are opposing each other, meaning that when the **door latch is closed** , switch 1 is in the open state and switch 2 is in the closed state. The opposite is true when the **door latch is opened** . For more information refer to the tables below.
- **Passenger Ajar Switches:** The ajar switches are open when the latch is closed. When the door latch is ajar the switch closes allowing the signal to connect to ground through the switch. Therefore the signal inputs to the BCM are high when the door is closed and low when the door is ajar.

The BCM monitors the Driver Door Ajar Switch signal circuit and converts the voltage signal into counts to broadcast over the CAN Bus network.

- Electronic Control Modules read an analog signal voltage and converts it to digital counts. Each count is an equal percentage of the signal reference voltage. This can be seen when viewing some sensor or switch voltages and converted values on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts to a battery voltage reference.
- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals are high resolution. This allows the module to read small changes over a wide range in a variable resistance sensor signal. These are typically used on a temperature, pressure, position or MUX type of sensor.
- Switches typically have a much lower resolution than sensors. This is because an ECU is generally looking for a switch to be in only a few positions that use fixed resistors. The lower resolution also helps the ECU to overcome some resistance in a circuit and still read the correct state. This also lowers the sensitivity to setting DTCs.
- The voltage and percentages can vary slightly with calibration changes. The voltage values and percentages in the table are approximate and can be slightly different. Typically, a failure will be noticeably different than the values in the table. The voltage ranges given are based on a nominal reference voltage of 13.5 volts. The voltage on the signal will change with system voltage but the percentage of system voltage should not change.

The Driver Door Ajar Switch signal voltage is divided into 15 counts typically. The table below shows the relation between the Driver Door Ajar Switch states and **approximate voltage percentages/ranges.**

DOOR AJAR SWITCH 1

VOLTAGE PERCENTAGE/VALUE TO SWITCH STATE			
Percentage of Battery Voltage	**Voltage Range @ 13.5 volts nominal**	**Door Latch Position**	**Ajar Switch State (Open/Closed)**
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	CLOSED	SWITCH OPEN
20 - 53%	Nominal: 4.5v Range: 2.7v- 6.3v	AJAR	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DOOR AJAR SWITCH 2

Percentage of Battery Voltage	Voltage Range @ 13.5 volts nominal	Door Latch Position	Ajar Switch State (Open/Closed)
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	AJAR	SWITCH OPEN
20- 53%	Nominal: 4.5v Range: 2.7v- 6.3v	CLOSED	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DIAGNOSTIC OVERVIEW-DOOR LOCK MOTORS AND SWITCHES:

- **Lock Motors:** The BCM is capable of detecting opens and shorts in the H-Bridge control circuits. The locks are not thermally protected by the BCM. The protection is done by limiting the number of actuations within a calibrated time period.
- **Door Latch Switches:** The resistors in the latch switches allows the BCM to perform diagnostics on the circuits and switches. Unlike the passenger door switches the voltage on the two signals should not be high or low. If the BCM determines that either signal falls into the high or low range, a fault is set. If the door latch positions do not match between the two Driver Door Ajar Switches, a correlation fault will set.

WHEN MONITORED

- This diagnostic runs continuously with the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Primary Driver Door Ajar Switch signal voltage received over the CAN C BUS from the Body Control Module (BCM) is below a calibrated threshold.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
DRIVER DOOR LATCH AJAR SWITCH SENSE CIRCUIT SHORTED TO GROUND
DRIVER DOOR LATCH AJAR SWITCH SENSE CIRCUIT SHORTED TO THE DRIVER DOOR LATCH RETURN CIRCUIT
DRIVER DOOR LATCH
BODY CONTROL MODULE (BCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to **PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .**

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
   1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

      Are there any applicable Service Bulletins or Flash updates?

      Yes

- Perform the applicable repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **DISCONNECT THE DRIVER DOOR LATCH HARNESS CONNECTOR AND VERIFY THE ABILITY OF THE BCM TO READ THE B1811-DRIVER DOOR AJAR INPUT CIRCUIT HIGH DTC**
    1. The Electronic Control Unit (ECU) harness connectors must be connected to the ECU during this test step.
    2. With the ignition in the off position, disconnect the sensor harness connector.
    3. Turn the ignition on.
    4. With the scan tool, read DTCs.

    Does the scan tool display the B1811-DRIVER DOOR AJAR INPUT CIRCUIT HIGH with the connector disconnected?

    Yes

    - Replace the faulty switch (door latch) in accordance with the Service Information. Refer to **LATCH, DOOR, REMOVAL AND INSTALLATION** .
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

    No

    - Go To 4
4. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (G75) AJAR SWITCH SENSE CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.

2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
3. Connect the negative lead of the Digital Volt Ohm Meter DVOM to a known good ground.
4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- Go To 5

5. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (G75) AJAR SWITCH SENSE CIRCUIT FOR A SHORT TO THE DRIVER DOOR LATCH (P371) RETURN CIRCUIT**
    1. The ignition must be off when checking for a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: **There should be no continuity between the circuits being tested.**

    Is there continuity between the circuits?

    Yes

    - Repair the short between the circuits.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 6

6. **CHECK RELATED BCM AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.

4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
    - Proper connector installation.
    - Damaged connector locks.
    - Corrosion.
    - Other signs of water intrusion.
    - Weather seal damage (if equipped).
    - Bent terminals.
    - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
    - Terminals that have been pushed back into the connector cavity.
    - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Body Control Module (BCM) in accordance with the Service Information. Refer to **MODULE, BODY CONTROL (BCM), REMOVAL AND INSTALLATION** .
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B1811-DRIVER DOOR AJAR INPUT CIRCUIT HIGH

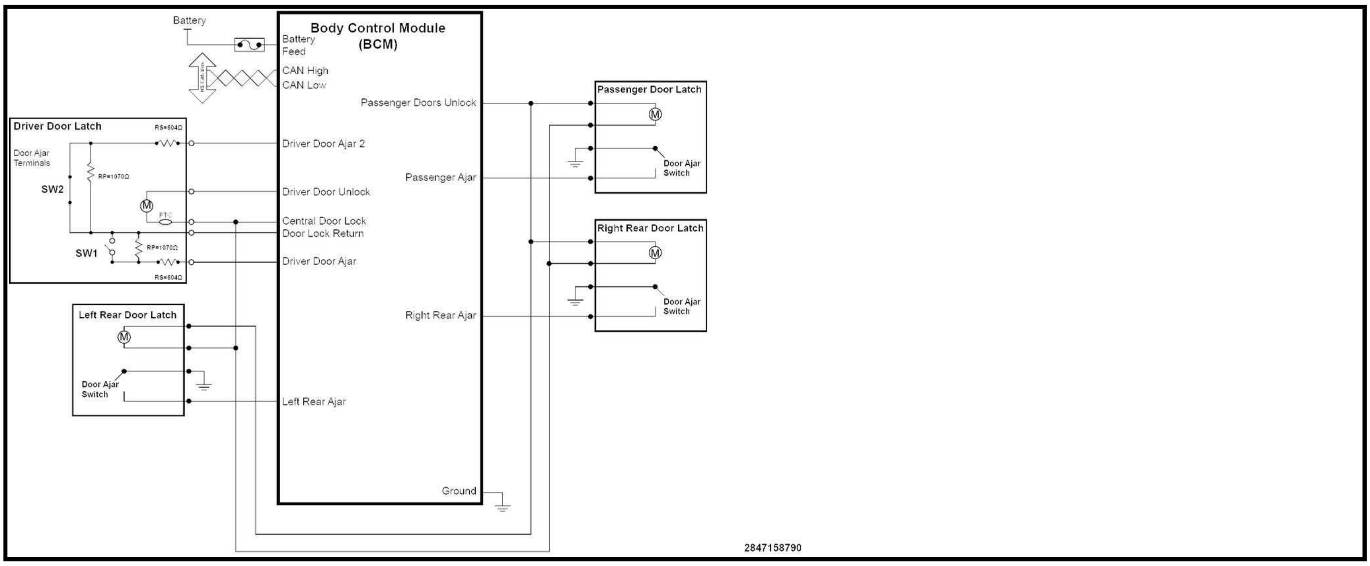
For a complete DOORS/LOCK SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Powertrain Control Module (PCM) receives the state (open/closed) of each switch over the CAN Bus from the Drivers Door Module (DDM) or Body Control Module (BCM) depending on the vehicles configuration and which module the latches are hard-wired to. The PCM continuously monitors the functioning status of the Driver Door Ajar Switch states for the operation of certain features such as Electric Stop/Start (ESS).

For further information on the effect of this DTC to the operation of ESS, see **ENGINE START/STOP (ESS) INOPERATIVE.** . Refer to **ENGINE STOP/START (ESS) SYSTEM INOPERATIVE** .

COMPONENT FUNCTIONAL DESCRIPTION - DOOR LATCH SYSTEM



Functional Operation of the Lock Motors: The Body Control Module (BCM) uses an H-Bridge configuration to drive the lock/unlock motors. To lock the doors, voltage is applied to the Lock pin circuit and ground is applied to both Unlock pin circuits. To unlock the doors, voltage is applied to the Unlock pins and ground is applied to the Lock pin. The passenger doors have a separate Unlock pin so that only the Driver's Door can be unlocked with the first button press on the keyless remote. When the lock motors are activated BCM will drive the motors for approximately 370 ms. The BCM and lock motors operate in the voltage range of 9.0 and 16.0 volts. Typical current draw for the motors are listed in Amps in the table below.

NOTE: The amperage values listed in the table are approximate.

BATTERY VOLTAGE	IN-RUSH CURRENT	CONTINUOUS OPERATION (NO LOAD)	STALL CURRENT
9.0	3.9	3.1	4.3
12.0	5.22	1.75	6.2
13.5	5.8	1.5	6.9
16.0	6.7	2.0	7.0

Functional Operation of the Latch Switches: All of the Door Latches are monitored to determine if they are closed or ajar. All of the ajar switches are wake-up signals to the BCM. The Driver Door Latch must be rationalized in order for some vehicle features to function. Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Door Ajar Switch signals use Battery voltage for a reference. The switches operate in the following manner:

- **Driver Door Ajar Switches:** The BCM has an internal pull up 1000 Ohm resistor for each ajar signal. Each switch has an internal 604 Ohm and 1070 Ohm resistor. When the switches are open the resistance through the switches are 1674 Ohms. When the switches are closed the resistance through the switches are 604 Ohms. The switch states are opposing each other, meaning that when the **door latch is closed** , switch 1 is in the open state and switch 2 is in the closed state. The opposite is true when the **door latch is opened** . For more information refer to the tables below.
- **Passenger Ajar Switches:** The ajar switches are open when the latch is closed. When the door latch is ajar the switch closes allowing the signal to connect to ground through the switch. Therefore the signal inputs to the BCM are high when the door is closed and low when the door is ajar.

The BCM monitors the Driver Door Ajar Switch signal circuit and converts the voltage signal into counts to broadcast over the CAN Bus network.

- Electronic Control Modules read an analog signal voltage and converts it to digital counts. Each count is an equal percentage of the signal reference voltage. This can be seen when viewing some sensor or switch voltages and converted values on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts to a battery voltage reference.

- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals are high resolution. This allows the module to read small changes over a wide range in a variable resistance sensor signal. These are typically used on a temperature, pressure, position or MUX type of sensor.
- Switches typically have a much lower resolution than sensors. This is because an ECU is generally looking for a switch to be in only a few positions that use fixed resistors. The lower resolution also helps the ECU to overcome some resistance in a circuit and still read the correct state. This also lowers the sensitivity to setting DTCs.
- The voltage and percentages can vary slightly with calibration changes. The voltage values and percentages in the table are approximate and can be slightly different. Typically, a failure will be noticeably different than the values in the table. The voltage ranges given are based on a nominal reference voltage of 13.5 volts. The voltage on the signal will change with system voltage but the percentage of system voltage should not change.

The Driver Door Ajar Switch signal voltage is divided into 15 counts typically. The table below shows the relation between the Driver Door Ajar Switch states and **approximate voltage percentages/ranges.**

DOOR AJAR SWITCH 1

VOLTAGE PERCENTAGE/VALUE TO SWITCH STATE			
Percentage of Battery Voltage	**Voltage Range @ 13.5 volts nominal**	**Door Latch Position**	**Ajar Switch State (Open/Closed)**
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	CLOSED	SWITCH OPEN
20 - 53%	Nominal: 4.5v Range: 2.7v- 6.3v	AJAR	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DOOR AJAR SWITCH 2

Percentage of Battery Voltage	Voltage Range @ 13.5 volts nominal	Door Latch Position	Ajar Switch State (Open/Closed)
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	AJAR	SWITCH OPEN
20- 53%	Nominal: 4.5v Range: 2.7v- 6.3v	CLOSED	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DIAGNOSTIC OVERVIEW-DOOR LOCK MOTORS AND SWITCHES:

- **Lock Motors:** The BCM is capable of detecting opens and shorts in the H-Bridge control circuits. The locks are not thermally protected by the BCM. The protection is done by limiting the number of actuations within a calibrated time period.
- **Door Latch Switches:** The resistors in the latch switches allows the BCM to perform diagnostics on the circuits and switches. Unlike the passenger door switches the voltage on the two signals should not be

high or low. If the BCM determines that either signal falls into the high or low range, a fault is set. If the door latch positions do not match between the two Driver Door Ajar Switches, a correlation fault will set.

WHEN MONITORED

- This diagnostic runs continuously with the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Primary Driver Door Ajar Switch signal voltage received over the CAN C BUS from the Body Control Module (BCM) is above a calibrated threshold.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
DRIVER DOOR LATCH AJAR SWITCH SENSE CIRCUIT SHORTED TO VOLTAGE
DRIVER DOOR LATCH AJAR SWITCH SENSE CIRCUIT OPEN/HIGH RESISTANCE
DRIVER DOOR LATCH RETURN CIRCUIT OPEN/HIGH RESISTANCE
DOOR LATCH
BODY CONTROL MODULE (BCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

        Are there any applicable Service Bulletins or Flash updates?

        Yes

        - Perform the applicable repair.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.

7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 3

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **CHECK THE DRIVER DOOR LATCH (G75) AJAR SWITCH SENSE CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

NOTE:	The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.

Is the voltage above 5.2 volts?

Yes

- Go To 4

No

- Go To 5

4. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (G75) AJAR SWITCH SENSE CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

NOTE:	With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- Go To 8

5. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (G75) AJAR SWITCH SENSE CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the ECU harness connector and measure the resistance of the circuit.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 6

    No

    - Repair the circuit for an open or high resistance.
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

6. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (P371) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

        NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

        Is the resistance below 3.0 Ohms?

        Yes

        - Go To 7

        No

        - Repair the circuit for an open or high resistance.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **CONNECT A FUSED JUMPER BETWEEN THE DRIVER DOOR LATCH (G75) AJAR SWITCH SENSE CIRCUIT AND THE DRIVER DOOR LATCH (P371) RETURN CIRCUIT AT THE DOOR LATCH HARNESS CONNECTOR - VERIFY ABILITY OF THE BCM TO DETECT THE B1810-DRIVER DOOR AJAR INPUT CIRCUIT LOW DTC**
   1. The Electronic Control Unit (ECU) harness connectors must be connected to the ECU during this test step.
   2. Disconnect the sensor harness connector.
   3. With the ignition in the off position, connect a fused jumper between the sensor signal circuit and the sensor ground circuit at the sensor harness connector.
   4. Turn the ignition on.
   5. With the scan tool, read DTCs.

   Does the scan tool display the B1810-DRIVER DOOR AJAR INPUT CIRCUIT LOW with the jumper in place?

   Yes

   - Replace the faulty switch (door latch) in accordance with the Service Information. Refer to **LATCH, DOOR, REMOVAL AND INSTALLATION** .
   - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

   No

   - Go To 8
8. **CHECK RELATED BCM AND COMPONENT CONNECTIONS**
   1. Disconnect all BCM harness connectors.
   2. Disconnect all related in-line harness connections (if equipped).
   3. Disconnect the related component harness connectors.
   4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.
   5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. With the scan tool, erase DTCs.

9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Body Control Module (BCM) in accordance with the Service Information. Refer to **MODULE, BODY CONTROL (BCM), REMOVAL AND INSTALLATION** .
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B1BE3-DRIVER PRESENCE DETECTION SENSOR PERFORMANCE

WHEN MONITORED

- This diagnostic runs continuously with the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) receives over the CAN Bus a message from the Driver Presence Detection Module (DPDM) that an error is being detected.

DEFAULT ACTION

- This is a non MIL fault.

POSSIBLE CAUSES

Possible Causes
DRIVER PRESENCE DETECTION MODULE (DPDM) DTCS PRESENT
DRIVER PRESENCE DETECTION MODULE (DPDM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to **PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE** .

DIAGNOSTIC TEST

1. **CHECK FOR DPDM MODULE DTCS**
    1. With the scan tool, read Driver Presence Detection Module (DPDM) DTCs.

        Are there any DPDM DTCs present?

        Yes

        - Perform the appropriate DPDM diagnostic procedure(s). Refer to **DIAGNOSIS AND TESTING** .

        No

        - Go To 2
2. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

Are there any applicable Service Bulletins or Flash updates?

Yes

- Perform the applicable repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 3

3. **CHECK RELATED DPDM MODULE AND COMPONENT CONNECTIONS**
    1. Turn the ignition off.
    2. Disconnect all DPDM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all DPDM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Driver Presence Detection Module (DPDM) in accordance with the Service information. Refer to **MODULE, DRIVER PRESENCE DETECTION (DPDM), REMOVAL AND INSTALLATION** .
        - Perform the DPDM VERIFICATION TEST. Refer to **DRIVER PRESENCE DETECTION MODULE (DPDM) VERIFICATION TEST** .

        No

- The wiring or poor connection problem has been repaired.
- Perform the DPDM VERIFICATION TEST. Refer to **DRIVER PRESENCE DETECTION MODULE (DPDM) VERIFICATION TEST** .

B1BE7-DRIVER PRESENCE DETECTION SENSOR CIRCUIT LOW

WHEN MONITORED

- This diagnostic runs continuously with the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) receives a message from the Driver Presence Detection Module (DPDM) over the CAN Bus that a short to ground on the sensor circuit is detected.

DEFAULT ACTION

- This is a non MIL fault.

POSSIBLE CAUSES

Possible Causes
DRIVER PRESENCE DETECTION MODULE (DPDM) DTCS PRESENT
DRIVER PRESENCE DETECTION MODULE (DPDM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to **PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE** .

DIAGNOSTIC TEST

1. **CHECK FOR DPDM MODULE DTCS**
    1. With the scan tool, read Driver Presence Detection Module (DPDM) DTCs.

        Are there any DPDM DTCs present?

        Yes

        - Perform the appropriate DPDM diagnostic procedure(s). Refer to **DIAGNOSIS AND TESTING** .

        No

        - Go To 2
2. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

        Are there any applicable Service Bulletins or Flash updates?

        Yes

        - Perform the applicable repair.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Go To 3
3. **CHECK RELATED DPDM MODULE AND COMPONENT CONNECTIONS**

1. Turn the ignition off.
2. Disconnect all DPDM harness connectors.
3. Disconnect all related in-line harness connections (if equipped).
4. Disconnect the related component harness connectors.
5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
   - Proper connector installation.
   - Damaged connector locks.
   - Corrosion.
   - Other signs of water intrusion.
   - Weather seal damage (if equipped).
   - Bent terminals.
   - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
   - Terminals that have been pushed back into the connector cavity.
   - Check for spread terminals and verify proper terminal tension.

   Repair any conditions that are found.
6. Reconnect all DPDM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Driver Presence Detection Module (DPDM) in accordance with the Service information. Refer to **MODULE, DRIVER PRESENCE DETECTION (DPDM), REMOVAL AND INSTALLATION** .
    - Perform the DPDM VERIFICATION TEST. Refer to **DRIVER PRESENCE DETECTION MODULE (DPDM) VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the DPDM VERIFICATION TEST. Refer to **DRIVER PRESENCE DETECTION MODULE (DPDM) VERIFICATION TEST** .

B1BE9-DRIVER PRESENCE DETECTION SENSOR CIRCUIT HIGH

WHEN MONITORED

- This diagnostic runs continuously with the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) receives over the CAN Bus a message from the Driver Presence Detection Module (DPDM) that an short to voltage on the sensor circuit is being detected.

DEFAULT ACTION

- This is a non MIL fault.

POSSIBLE CAUSES

Possible Causes
DRIVER PRESENCE DETECTION MODULE (DPDM) DTCS PRESENT
DRIVER PRESENCE DETECTION MODULE (DPDM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to **PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE** .

DIAGNOSTIC TEST

1. **CHECK FOR DPDM MODULE DTCS**
    1. With the scan tool, read Driver Presence Detection Module (DPDM) DTCs.

       Are there any DPDM DTCs present?

       Yes

       - Perform the appropriate DPDM diagnostic procedure(s). Refer to **DIAGNOSIS AND TESTING** .

       No

       - Go To 2
2. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 3
3. **CHECK RELATED DPDM MODULE AND COMPONENT CONNECTIONS**
    1. Turn the ignition off.
    2. Disconnect all DPDM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all DPDM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Driver Presence Detection Module (DPDM) in accordance with the Service information. Refer to **MODULE, DRIVER PRESENCE DETECTION (DPDM), REMOVAL AND INSTALLATION** .
- Perform the DPDM VERIFICATION TEST. Refer to **DRIVER PRESENCE DETECTION MODULE (DPDM) VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the DPDM VERIFICATION TEST. Refer to **DRIVER PRESENCE DETECTION MODULE (DPDM) VERIFICATION TEST** .

B23BB-STOP/START DISABLE SWITCH 1 CIRCUIT OPEN

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine running for more than five seconds.
- Battery voltage between 10.0 and 15.75 volts.

SET CONDITION

- The Powertrain Control Module (PCM) receives the Stop/Start Disable Switch voltage input over CAN Bus from the Integrated Center Stack (ICS) Switch Bank Module. The PCM detects an open in the Stop/Start Disable Switch input for more than 2.24 seconds.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INTEGRATED CENTER STACK (ICS) SWITCH BANK MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK RELATED INTEGRATED CENTER STACK AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.

- Corrosion.
- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Integrated Center Stack (ICS) in accordance with the Service Information. Refer to **MODULE, INTEGRATED CENTER STACK (ICSM), REMOVAL AND INSTALLATION** .
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B23BC-STOP/START DISABLE SWITCH 1 CIRCUIT PERFORMANCE

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine running for more than five seconds.
- Battery voltage between 10.0 and 15.75 volts.

SET CONDITION

- The Powertrain Control Module (PCM) receives the Stop/Start Disable Switch voltage input over CAN Bus from the Integrated Center Stack (ICS) Switch Bank Module. The PCM detects that the Stop/Start Disable Switch 1 input is irrational.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INTEGRATED CENTER STACK (ICS) SWITCH BANK MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK RELATED INTEGRATED CENTER STACK AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Integrated Center Stack (ICS) in accordance with the Service Information. Refer to **MODULE, INTEGRATED CENTER STACK (ICSM), REMOVAL AND INSTALLATION** .
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B23BD-STOP/START DISABLE SWITCH 1 CIRCUIT LOW

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine running for more than five seconds.
- Battery voltage between 10.0 and 15.75 volts.

SET CONDITION

- The Powertrain Control Module (PCM) receives the Stop/Start Disable Switch voltage input over CAN Bus from the Integrated Center Stack (ICS) Switch Bank Module. The PCM detects that the Stop/Start Disable Switch 1 circuit voltage is less than 0.004 volts.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INTEGRATED CENTER STACK (ICS) SWITCH BANK MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK RELATED INTEGRATED CENTER STACK AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Integrated Center Stack (ICS) in accordance with the Service Information. Refer to **MODULE, INTEGRATED CENTER STACK (ICSM), REMOVAL AND INSTALLATION** .
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B23BE-STOP/START DISABLE SWITCH 1 CIRCUIT HIGH

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine running for more than five seconds.
- Battery voltage between 10.0 and 15.75 volts.

SET CONDITION

- The Powertrain Control Module (PCM) receives the Stop/Start Disable Switch voltage input over CAN Bus from the Integrated Center Stack (ICS) Switch Bank Module. The PCM detects an open in the Stop/Start Disable Switch 2 input for more than 2.24 seconds.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INTEGRATED CENTER STACK (ICS) SWITCH BANK MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK RELATED INTEGRATED CENTER STACK AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Integrated Center Stack (ICS) in accordance with the Service Information. Refer to **MODULE, INTEGRATED CENTER STACK (ICSM), REMOVAL AND INSTALLATION** .
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B23BF-STOP/START DISABLE SWITCH 2 CIRCUIT OPEN

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine running for more than five seconds.
- Battery voltage between 10.0 and 15.75 volts.

SET CONDITION

- The Powertrain Control Module (PCM) receives the Stop/Start Disable Switch voltage input over CAN Bus from the Integrated Center Stack (ICS) Switch Bank Module. The PCM detects an open in the Stop/Start Disable Switch 2 input for more than 2.24 seconds.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INTEGRATED CENTER STACK (ICS) SWITCH BANK MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK RELATED INTEGRATED CENTER STACK AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Integrated Center Stack (ICS) in accordance with the Service Information. Refer to **MODULE, INTEGRATED CENTER STACK (ICSM), REMOVAL AND INSTALLATION** .
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B23C0-STOP/START DISABLE SWITCH 2 CIRCUIT PERFORMANCE

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine running for more than five seconds.
- Battery voltage between 10.0 and 15.75 volts.

SET CONDITION

- The Powertrain Control Module (PCM) receives the Stop/Start Disable Switch voltage input over CAN Bus from the Integrated Center Stack (ICS) Switch Bank Module. The PCM detects that the Stop/Start Disable Switch 2 input is irrational.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INTEGRATED CENTER STACK (ICS) SWITCH BANK MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK RELATED INTEGRATED CENTER STACK AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Integrated Center Stack (ICS) in accordance with the Service Information. Refer to **MODULE, INTEGRATED CENTER STACK (ICSM), REMOVAL AND INSTALLATION** .
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B23C1-STOP/START DISABLE SWITCH 2 CIRCUIT LOW

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine running for more than five seconds.
- Battery voltage between 10.0 and 15.75 volts.

SET CONDITION

- The Powertrain Control Module (PCM) receives the Stop/Start Disable Switch voltage input over CAN BUS from the Integrated Center Stack (ICS) Switch Bank Module. The PCM detects that the Stop/Start Disable Switch 2 circuit voltage is less than 0.004 volts.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INTEGRATED CENTER STACK (ICS) SWITCH BANK MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK RELATED INTEGRATED CENTER STACK AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Integrated Center Stack (ICS) in accordance with the Service Information. Refer to **MODULE, INTEGRATED CENTER STACK (ICSM), REMOVAL AND INSTALLATION** .
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B23C2-STOP/START DISABLE SWITCH 2 CIRCUIT HIGH

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine running for more than five seconds.
- Battery voltage between 10.0 and 15.75 volts.

SET CONDITION

- The Powertrain Control Module (PCM) receives the Stop/Start Disable Switch voltage input over CAN BUS from the Integrated Center Stack (ICS) Switch Bank Module. The PCM detects that the Stop/Start Disable Switch 2 circuit voltage is greater than 4.9 volts.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INTEGRATED CENTER STACK (ICS) SWITCH BANK MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK RELATED INTEGRATED CENTER STACK AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.

    - Other signs of water intrusion.
    - Weather seal damage (if equipped).
    - Bent terminals.
    - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
    - Terminals that have been pushed back into the connector cavity.
    - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.
5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Integrated Center Stack (ICS) in accordance with the Service Information. Refer to **MODULE, INTEGRATED CENTER STACK (ICSM), REMOVAL AND INSTALLATION** .
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B23C3-STOP/START DISABLE SWITCH 1/2 CORRELATION

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine running for more than five seconds.
- Battery voltage between 10.0 and 15.75 volts.

SET CONDITION

- The Powertrain Control Module (PCM) receives the Stop/Start Disable Switch voltage input over Controlled Area Network (CAN) Bus from the Integrated Center Stack (ICS) Switch Bank Module. The PCM detects that the difference between the Stop/Start Disable Switch 1 and Switch 2 circuit voltages are greater than 1.0 volt for more than 0.08 seconds.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this Diagnostic Trouble Code (DTC) is active.

POSSIBLE CAUSES

Possible Causes
INTEGRATED CENTER STACK (ICS) SWITCH BANK MODULE

Always perform the Pre-Diagnostic Troubleshooting procedure before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK RELATED INTEGRATED CENTER STACK AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Integrated Center Stack (ICS) in accordance with the Service Information. Refer to **MODULE, INTEGRATED CENTER STACK (ICSM), REMOVAL AND INSTALLATION** .
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B25BC-LEFT FRONT DOOR AJAR SWITCH STUCK CLOSED

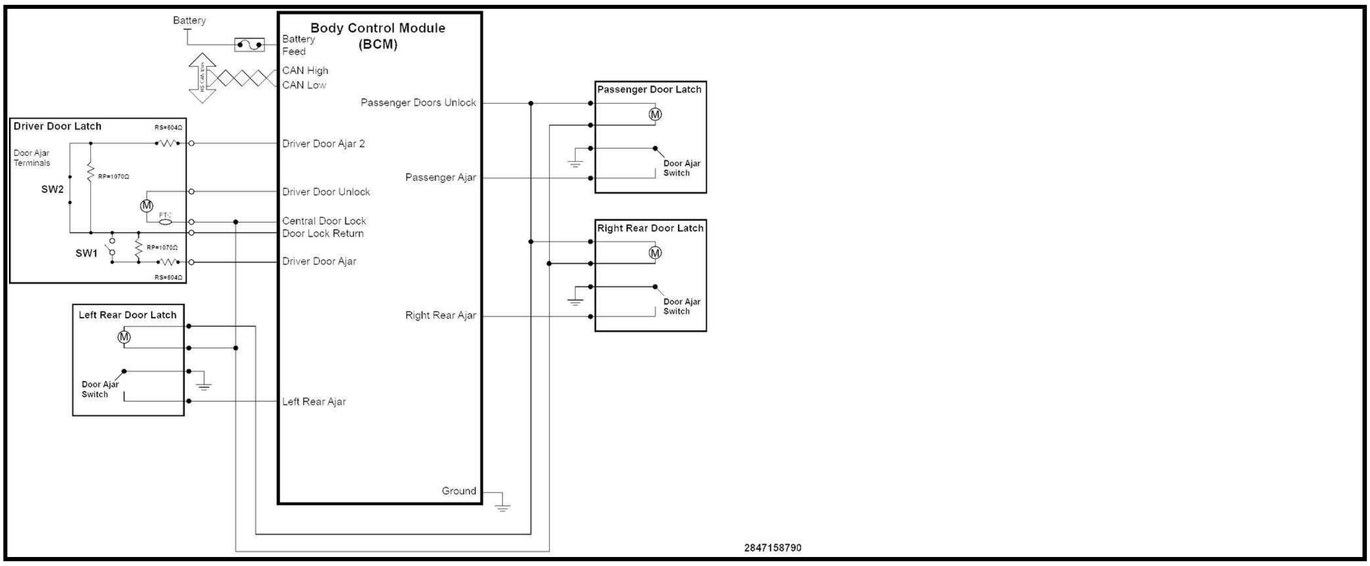
For a complete DOORS/LOCK SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Powertrain Control Module (PCM) receives the state (open/closed) of each switch over the CAN Bus from the Drivers Door Module (DDM) or Body Control Module (BCM) depending on the vehicles configuration and which module the latches are hard-wired to. The PCM continuously monitors the functioning status of the Driver Door Ajar Switch states for the operation of certain features such as Electric Stop/Start (ESS).

For further information on the effect of this DTC to the operation of ESS, see **ENGINE START/STOP (ESS) INOPERATIVE.** . Refer to **ENGINE STOP/START (ESS) SYSTEM INOPERATIVE** .

COMPONENT FUNCTIONAL DESCRIPTION - DOOR LATCH SYSTEM



Functional Operation of the Lock Motors: The Body Control Module (BCM) uses an H-Bridge configuration to drive the lock/unlock motors. To lock the doors, voltage is applied to the Lock pin circuit and ground is applied to both Unlock pin circuits. To unlock the doors, voltage is applied to the Unlock pins and ground is applied to the Lock pin. The passenger doors have a separate Unlock pin so that only the Driver's Door can be unlocked with the first button press on the keyless remote. When the lock motors are activated BCM will drive the motors for approximately 370 ms. The BCM and lock motors operate in the voltage range of 9.0 and 16.0 volts. Typical current draw for the motors are listed in Amps in the table below.

NOTE: **The amperage values listed in the table are approximate.**

BATTERY VOLTAGE	IN-RUSH CURRENT	CONTINUOUS OPERATION (NO LOAD)	STALL CURRENT
9.0	3.9	3.1	4.3
12.0	5.22	1.75	6.2
13.5	5.8	1.5	6.9
16.0	6.7	2.0	7.0

Functional Operation of the Latch Switches: All of the Door Latches are monitored to determine if they are closed or ajar. All of the ajar switches are wake-up signals to the BCM. The Driver Door Latch must be rationalized in order for some vehicle features to function. Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Door Ajar Switch signals use Battery voltage for a reference. The switches operate in the following manner:

- **Driver Door Ajar Switches:** The BCM has an internal pull up 1000 Ohm resistor for each ajar signal. Each switch has an internal 604 Ohm and 1070 Ohm resistor. When the switches are open the resistance through the switches are 1674 Ohms. When the switches are closed the resistance through the switches are 604 Ohms. The switch states are opposing each other, meaning that when the **door latch is closed** , switch 1 is in the open state and switch 2 is in the closed state. The opposite is true when the **door latch is opened** . For more information refer to the tables below.
- **Passenger Ajar Switches:** The ajar switches are open when the latch is closed. When the door latch is ajar the switch closes allowing the signal to connect to ground through the switch. Therefore the signal inputs to the BCM are high when the door is closed and low when the door is ajar.

The BCM monitors the Driver Door Ajar Switch signal circuit and converts the voltage signal into counts to broadcast over the CAN Bus network.

- Electronic Control Modules read an analog signal voltage and converts it to digital counts. Each count is an equal percentage of the signal reference voltage. This can be seen when viewing some sensor or switch voltages and converted values on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts to a battery voltage reference.

- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals are high resolution. This allows the module to read small changes over a wide range in a variable resistance sensor signal. These are typically used on a temperature, pressure, position or MUX type of sensor.
- Switches typically have a much lower resolution than sensors. This is because an ECU is generally looking for a switch to be in only a few positions that use fixed resistors. The lower resolution also helps the ECU to overcome some resistance in a circuit and still read the correct state. This also lowers the sensitivity to setting DTCs.
- The voltage and percentages can vary slightly with calibration changes. The voltage values and percentages in the table are approximate and can be slightly different. Typically, a failure will be noticeably different than the values in the table. The voltage ranges given are based on a nominal reference voltage of 13.5 volts. The voltage on the signal will change with system voltage but the percentage of system voltage should not change.

The Driver Door Ajar Switch signal voltage is divided into 15 counts typically. The table below shows the relation between the Driver Door Ajar Switch states and **approximate voltage percentages/ranges.**

DOOR AJAR SWITCH 1

VOLTAGE PERCENTAGE/VALUE TO SWITCH STATE			
Percentage of Battery Voltage	**Voltage Range @ 13.5 volts nominal**	**Door Latch Position**	**Ajar Switch State (Open/Closed)**
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	CLOSED	SWITCH OPEN
20 - 53%	Nominal: 4.5v Range: 2.7v- 6.3v	AJAR	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DOOR AJAR SWITCH 2

Percentage of Battery Voltage	**Voltage Range @ 13.5 volts nominal**	**Door Latch Position**	**Ajar Switch State (Open/Closed)**
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	AJAR	SWITCH OPEN
20- 53%	Nominal: 4.5v Range: 2.7v- 6.3v	CLOSED	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DIAGNOSTIC OVERVIEW-DOOR LOCK MOTORS AND SWITCHES:

- **Lock Motors:** The BCM is capable of detecting opens and shorts in the H-Bridge control circuits. The locks are not thermally protected by the BCM. The protection is done by limiting the number of actuations within a calibrated time period.
- **Door Latch Switches:** The resistors in the latch switches allows the BCM to perform diagnostics on the circuits and switches. Unlike the passenger door switches the voltage on the two signals should not be

high or low. If the BCM determines that either signal falls into the high or low range, a fault is set. If the door latch positions do not match between the two Driver Door Ajar Switches, a correlation fault will set.

WHEN MONITORED

- This diagnostic runs continuously with the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) receives the door ajar status over the CAN C BUS from the Body Control Module (BCM). The PCM detects that the Driver Door Latch Ajar Switch state is stuck closed.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
LEFT FRONT DOOR LATCH WIRING ISSUE
LEFT FRONT DOOR LATCH ASSEMBLY
BODY CONTROL MODULE (BCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. Open and close the door several times.
    8. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 3

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are there any Door Ajar Switch circuit high or low faults present?

      Yes

      - Perform the applicable diagnostic procedure(s).

      No

      - Go To 4
4. **REPLACE THE LEFT FRONT DOOR LATCH ASSEMBLY AND RETEST FOR DTCS**
   1. Turn the ignition off.
   2. Replace the component (Door Latch) in accordance with the Service Information.
   3. Connect the component and Electronic Control Unit (ECU) harness connectors.
   4. Turn the ignition on.
   5. With the scan tool, erase all DTCs.
   6. Turn the ignition off for a minimum of 10.0 seconds.
   7. Turn the ignition on.
   8. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
   9. Open and close the door several times.
   10. With the scan tool, read DTCs.

   Did the DTC return?

   Yes

   - Go To 5

   No

   - Replacing the faulty component repaired the fault.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
5. **CHECK RELATED BCM AND COMPONENT CONNECTIONS**
   1. Disconnect all BCM harness connectors.
   2. Disconnect all related in-line harness connections (if equipped).
   3. Disconnect the related component harness connectors.
   4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.

- Damaged connector locks.
- Corrosion.
- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Body Control Module (BCM) in accordance with the Service Information. Refer to **MODULE, BODY CONTROL (BCM), REMOVAL AND INSTALLATION** .
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B25C7-DRIVER DOOR AJAR SWITCH 2 CIRCUIT LOW

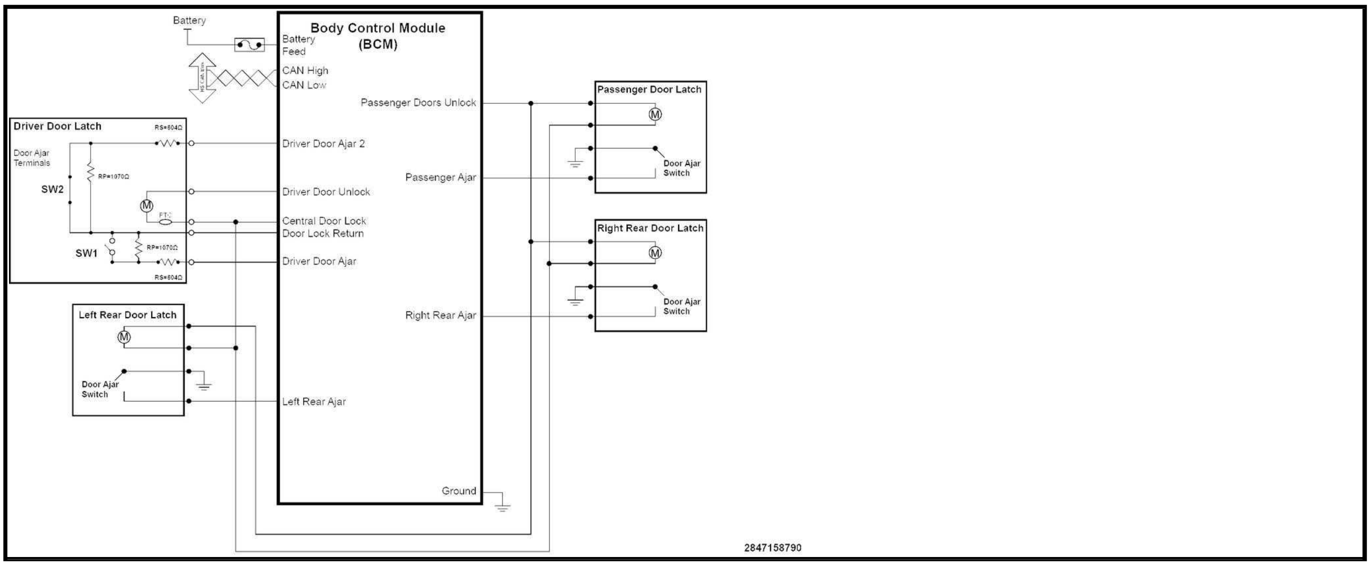
For a complete DOORS/LOCK SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Powertrain Control Module (PCM) receives the state (open/closed) of each switch over the CAN Bus from the Drivers Door Module (DDM) or Body Control Module (BCM) depending on the vehicles configuration and which module the latches are hard-wired to. The PCM continuously monitors the functioning status of the Driver Door Ajar Switch states for the operation of certain features such as Electric Stop/Start (ESS).

For further information on the effect of this DTC to the operation of ESS, see **ENGINE START/STOP (ESS) INOPERATIVE.** . Refer to **ENGINE STOP/START (ESS) SYSTEM INOPERATIVE** .

COMPONENT FUNCTIONAL DESCRIPTION - DOOR LATCH SYSTEM



Functional Operation of the Lock Motors: The Body Control Module (BCM) uses an H-Bridge configuration to drive the lock/unlock motors. To lock the doors, voltage is applied to the Lock pin circuit and ground is applied to both Unlock pin circuits. To unlock the doors, voltage is applied to the Unlock pins and ground is applied to the Lock pin. The passenger doors have a separate Unlock pin so that only the Driver's Door can be unlocked with the first button press on the keyless remote. When the lock motors are activated BCM will drive the motors for approximately 370 ms. The BCM and lock motors operate in the voltage range of 9.0 and 16.0 volts. Typical current draw for the motors are listed in Amps in the table below.

NOTE: **The amperage values listed in the table are approximate.**

BATTERY VOLTAGE	IN-RUSH CURRENT	CONTINUOUS OPERATION (NO LOAD)	STALL CURRENT
9.0	3.9	3.1	4.3
12.0	5.22	1.75	6.2
13.5	5.8	1.5	6.9
16.0	6.7	2.0	7.0

Functional Operation of the Latch Switches: All of the Door Latches are monitored to determine if they are closed or ajar. All of the ajar switches are wake-up signals to the BCM. The Driver Door Latch must be rationalized in order for some vehicle features to function. Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Door Ajar Switch signals use Battery voltage for a reference. The switches operate in the following manner:

- **Driver Door Ajar Switches:** The BCM has an internal pull up 1000 Ohm resistor for each ajar signal. Each switch has an internal 604 Ohm and 1070 Ohm resistor. When the switches are open the resistance through the switches are 1674 Ohms. When the switches are closed the resistance through the switches are 604 Ohms. The switch states are opposing each other, meaning that when the **door latch is closed** , switch 1 is in the open state and switch 2 is in the closed state. The opposite is true when the **door latch is opened** . For more information refer to the tables below.
- **Passenger Ajar Switches:** The ajar switches are open when the latch is closed. When the door latch is ajar the switch closes allowing the signal to connect to ground through the switch. Therefore the signal inputs to the BCM are high when the door is closed and low when the door is ajar.

The BCM monitors the Driver Door Ajar Switch signal circuit and converts the voltage signal into counts to broadcast over the CAN Bus network.

- Electronic Control Modules read an analog signal voltage and converts it to digital counts. Each count is an equal percentage of the signal reference voltage. This can be seen when viewing some sensor or switch voltages and converted values on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts to a battery voltage reference.

- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals are high resolution. This allows the module to read small changes over a wide range in a variable resistance sensor signal. These are typically used on a temperature, pressure, position or MUX type of sensor.
- Switches typically have a much lower resolution than sensors. This is because an ECU is generally looking for a switch to be in only a few positions that use fixed resistors. The lower resolution also helps the ECU to overcome some resistance in a circuit and still read the correct state. This also lowers the sensitivity to setting DTCs.
- The voltage and percentages can vary slightly with calibration changes. The voltage values and percentages in the table are approximate and can be slightly different. Typically, a failure will be noticeably different than the values in the table. The voltage ranges given are based on a nominal reference voltage of 13.5 volts. The voltage on the signal will change with system voltage but the percentage of system voltage should not change.

The Driver Door Ajar Switch signal voltage is divided into 15 counts typically. The table below shows the relation between the Driver Door Ajar Switch states and **approximate voltage percentages/ranges.**

DOOR AJAR SWITCH 1

VOLTAGE PERCENTAGE/VALUE TO SWITCH STATE			
Percentage of Battery Voltage	**Voltage Range @ 13.5 volts nominal**	**Door Latch Position**	**Ajar Switch State (Open/Closed)**
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	CLOSED	SWITCH OPEN
20 - 53%	Nominal: 4.5v Range: 2.7v- 6.3v	AJAR	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DOOR AJAR SWITCH 2

Percentage of Battery Voltage	Voltage Range @ 13.5 volts nominal	Door Latch Position	Ajar Switch State (Open/Closed)
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	AJAR	SWITCH OPEN
20- 53%	Nominal: 4.5v Range: 2.7v- 6.3v	CLOSED	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DIAGNOSTIC OVERVIEW-DOOR LOCK MOTORS AND SWITCHES:

- **Lock Motors:** The BCM is capable of detecting opens and shorts in the H-Bridge control circuits. The locks are not thermally protected by the BCM. The protection is done by limiting the number of actuations within a calibrated time period.
- **Door Latch Switches:** The resistors in the latch switches allows the BCM to perform diagnostics on the circuits and switches. Unlike the passenger door switches the voltage on the two signals should not be

high or low. If the BCM determines that either signal falls into the high or low range, a fault is set. If the door latch positions do not match between the two Driver Door Ajar Switches, a correlation fault will set.

WHEN MONITORED

- With the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Secondary Driver Door Ajar Switch signal voltage received over the CAN C BUS from the Body Control Module (BCM) is below a calibrated threshold.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
DRIVER DOOR LATCH AJAR SWITCH 2 SENSE CIRCUIT SHORTED TO GROUND
DRIVER DOOR LATCH AJAR SWITCH 2 SENSE CIRCUIT SHORTED TO THE DRIVER DOOR LATCH RETURN CIRCUIT
DRIVER DOOR LATCH
BODY CONTROL MODULE (BCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

        Are there any applicable Service Bulletins or Flash updates?

        Yes

        - Perform the applicable repair.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.

6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 3

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **DISCONNECT THE DRIVER DOOR LATCH HARNESS CONNECTOR AND VERIFY THE ABILITY OF THE BCM TO READ THE DRIVER DOOR AJAR SWITCH 2 CIRCUIT HIGH DTC**
    1. The Electronic Control Unit (ECU) harness connectors must be connected to the ECU during this test step.
    2. With the ignition in the off position, disconnect the sensor harness connector.
    3. Turn the ignition on.
    4. With the scan tool, read DTCs.

Does the scan tool display the B25C8-DRIVER DOOR AJAR SWITCH 2 CIRCUIT HIGH with the connector disconnected?

Yes

- Replace the Door Latch in accordance with the Service Information. Refer to **LATCH, DOOR, REMOVAL AND INSTALLATION** .
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- Go To 4

4. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (G755) AJAR SWITCH 2 SENSE CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

No

- Go To 5

5. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (G755) AJAR SWITCH 2 SENSE CIRCUIT FOR A SHORT TO THE DRIVER DOOR LATCH (P371) RETURN CIRCUIT**
    1. The ignition must be off when checking for a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

NOTE: **There should be no continuity between the circuits being tested.**

Is there continuity between the circuits?

Yes

- Repair the short between the circuits.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK RELATED BCM AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.

    5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. With the scan tool, erase DTCs.
    9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.

10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Body Control Module (BCM) in accordance with the Service Information. Refer to **MODULE, BODY CONTROL (BCM), REMOVAL AND INSTALLATION** .
    - Perform the BODY VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B25C8-DRIVER DOOR AJAR SWITCH 2 CIRCUIT HIGH

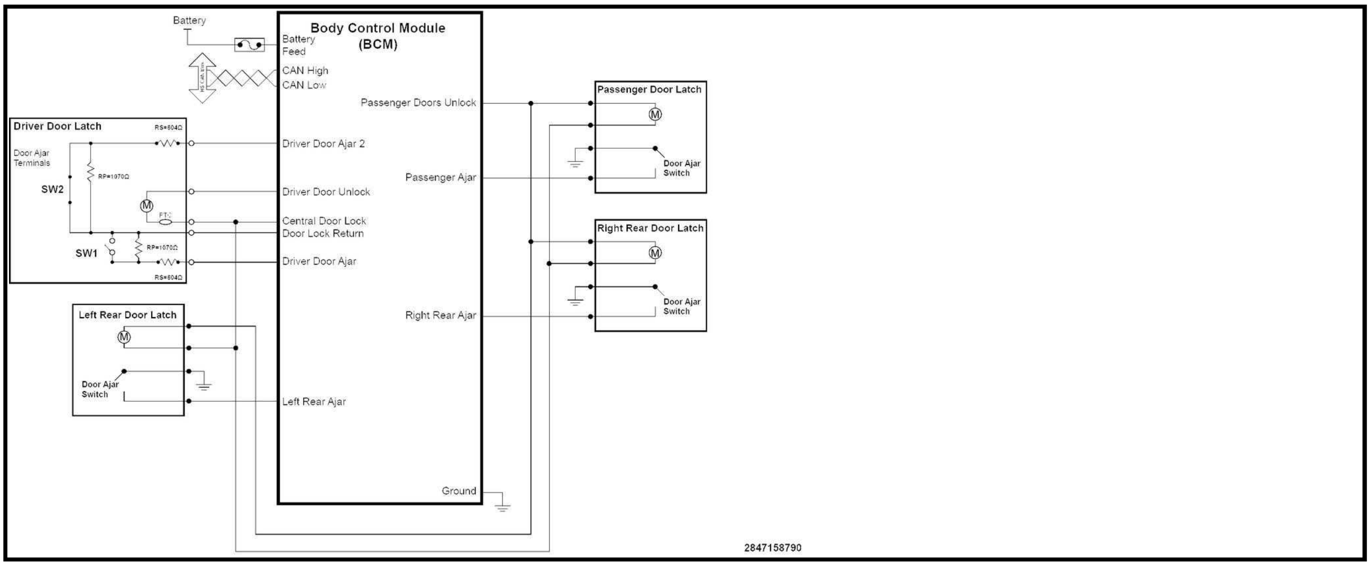
For a complete DOORS/LOCK SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Powertrain Control Module (PCM) receives the state (open/closed) of each switch over the CAN Bus from the Drivers Door Module (DDM) or Body Control Module (BCM) depending on the vehicles configuration and which module the latches are hard-wired to. The PCM continuously monitors the functioning status of the Driver Door Ajar Switch states for the operation of certain features such as Electric Stop/Start (ESS).

For further information on the effect of this DTC to the operation of ESS, see **ENGINE START/STOP (ESS) INOPERATIVE.** . Refer to **ENGINE STOP/START (ESS) SYSTEM INOPERATIVE** .

COMPONENT FUNCTIONAL DESCRIPTION - DOOR LATCH SYSTEM



Functional Operation of the Lock Motors: The Body Control Module (BCM) uses an H-Bridge configuration to drive the lock/unlock motors. To lock the doors, voltage is applied to the Lock pin circuit and ground is applied to both Unlock pin circuits. To unlock the doors, voltage is applied to the Unlock pins and ground is applied to the Lock pin. The passenger doors have a separate Unlock pin so that only the Driver's Door can be unlocked with the first button press on the keyless remote. When the lock motors are activated BCM will drive the motors for approximately 370 ms. The BCM and lock motors operate in the voltage range of 9.0 and 16.0 volts. Typical current draw for the motors are listed in Amps in the table below.

NOTE: **The amperage values listed in the table are approximate.**

BATTERY VOLTAGE	IN-RUSH CURRENT	CONTINUOUS OPERATION (NO LOAD)	STALL CURRENT
9.0	3.9	3.1	4.3
12.0	5.22	1.75	6.2
13.5	5.8	1.5	6.9
16.0	6.7	2.0	7.0

Functional Operation of the Latch Switches: All of the Door Latches are monitored to determine if they are closed or ajar. All of the ajar switches are wake-up signals to the BCM. The Driver Door Latch must be rationalized in order for some vehicle features to function. Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Door Ajar Switch signals use Battery voltage for a reference. The switches operate in the following manner:

- **Driver Door Ajar Switches:** The BCM has an internal pull up 1000 Ohm resistor for each ajar signal. Each switch has an internal 604 Ohm and 1070 Ohm resistor. When the switches are open the resistance through the switches are 1674 Ohms. When the switches are closed the resistance through the switches are 604 Ohms. The switch states are opposing each other, meaning that when the **door latch is closed** , switch 1 is in the open state and switch 2 is in the closed state. The opposite is true when the **door latch is opened** . For more information refer to the tables below.
- **Passenger Ajar Switches:** The ajar switches are open when the latch is closed. When the door latch is ajar the switch closes allowing the signal to connect to ground through the switch. Therefore the signal inputs to the BCM are high when the door is closed and low when the door is ajar.

The BCM monitors the Driver Door Ajar Switch signal circuit and converts the voltage signal into counts to broadcast over the CAN Bus network.

- Electronic Control Modules read an analog signal voltage and converts it to digital counts. Each count is an equal percentage of the signal reference voltage. This can be seen when viewing some sensor or switch voltages and converted values on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts to a battery voltage reference.
- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals are high resolution. This allows the module to read small changes over a wide range in a variable resistance sensor signal. These are typically used on a temperature, pressure, position or MUX type of sensor.
- Switches typically have a much lower resolution than sensors. This is because an ECU is generally looking for a switch to be in only a few positions that use fixed resistors. The lower resolution also helps the ECU to overcome some resistance in a circuit and still read the correct state. This also lowers the sensitivity to setting DTCs.
- The voltage and percentages can vary slightly with calibration changes. The voltage values and percentages in the table are approximate and can be slightly different. Typically, a failure will be noticeably different than the values in the table. The voltage ranges given are based on a nominal reference voltage of 13.5 volts. The voltage on the signal will change with system voltage but the percentage of system voltage should not change.

The Driver Door Ajar Switch signal voltage is divided into 15 counts typically. The table below shows the relation between the Driver Door Ajar Switch states and **approximate voltage percentages/ranges.**

DOOR AJAR SWITCH 1

VOLTAGE PERCENTAGE/VALUE TO SWITCH STATE			
Percentage of Battery Voltage	**Voltage Range @ 13.5 volts nominal**	**Door Latch Position**	**Ajar Switch State (Open/Closed)**
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	CLOSED	SWITCH OPEN
20 - 53%	Nominal: 4.5v Range: 2.7v- 6.3v	AJAR	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DOOR AJAR SWITCH 2

Percentage of Battery Voltage	Voltage Range @ 13.5 volts nominal	Door Latch Position	Ajar Switch State (Open/Closed)
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	AJAR	SWITCH OPEN
20- 53%	Nominal: 4.5v Range: 2.7v- 6.3v	CLOSED	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DIAGNOSTIC OVERVIEW-DOOR LOCK MOTORS AND SWITCHES:

- **Lock Motors:** The BCM is capable of detecting opens and shorts in the H-Bridge control circuits. The locks are not thermally protected by the BCM. The protection is done by limiting the number of actuations within a calibrated time period.
- **Door Latch Switches:** The resistors in the latch switches allows the BCM to perform diagnostics on the circuits and switches. Unlike the passenger door switches the voltage on the two signals should not be high or low. If the BCM determines that either signal falls into the high or low range, a fault is set. If the door latch positions do not match between the two Driver Door Ajar Switches, a correlation fault will set.

WHEN MONITORED

- With the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Secondary Driver Door Ajar Switch signal voltage received over the CAN C BUS from the Body Control Module (BCM) is above a calibrated threshold.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
DRIVER DOOR LATCH AJAR SWITCH 2 SENSE CIRCUIT OPEN/HIGH RESISTANCE

Possible Causes
DRIVER DOOR LATCH RETURN CIRCUIT OPEN/HIGH RESISTANCE
DRIVER DOOR LATCH
BODY CONTROL MODULE (BCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (G755) AJAR SWITCH 2 SENSE CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.

4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
5. Connect the other lead to the circuit being tested at the ECU harness connector and measure the resistance of the circuit.

Is the resistance below 3.0 Ohms?

Yes

- Go To 4

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (P371) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the ECU harness connector and measure the resistance of the circuit.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 5

    No

    - Repair the circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
5. **CONNECT A FUSED JUMPER BETWEEN THE DRIVER DOOR LATCH (G755) AJAR SWITCH 2 SENSE CIRCUIT AND THE DRIVER DOOR LATCH (P371) RETURN CIRCUIT AT THE DOOR LATCH HARNESS CONNECTOR - VERIFY ABILITY OF THE PCM TO DETECT THE SWITCH SIGNAL CIRCUIT LOW DTC**
    1. The Electronic Control Unit (ECU) harness connectors must be connected to the ECU during this test step.
    2. Disconnect the sensor harness connector.
    3. With the ignition in the off position, connect a fused jumper between the sensor signal circuit and the sensor ground circuit at the door latch harness connector.
    4. Turn the ignition on.
    5. With the scan tool, read DTCs.

    Does the scan tool display the B25C7-DRIVER DOOR AJAR SWITCH 2 CIRCUIT LOW with the jumper in place?

    Yes

- Replace the Door Latch in accordance with the Service Information. Refer to **LATCH, DOOR, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK RELATED BCM AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.

    5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. With the scan tool, erase DTCs.
    9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    10. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Body Control Module (BCM) in accordance with the Service Information. Refer to **MODULE, BODY CONTROL (BCM), REMOVAL AND INSTALLATION** .
        - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B25C9-DRIVER DOOR AJAR SWITCH 2 STUCK CLOSED

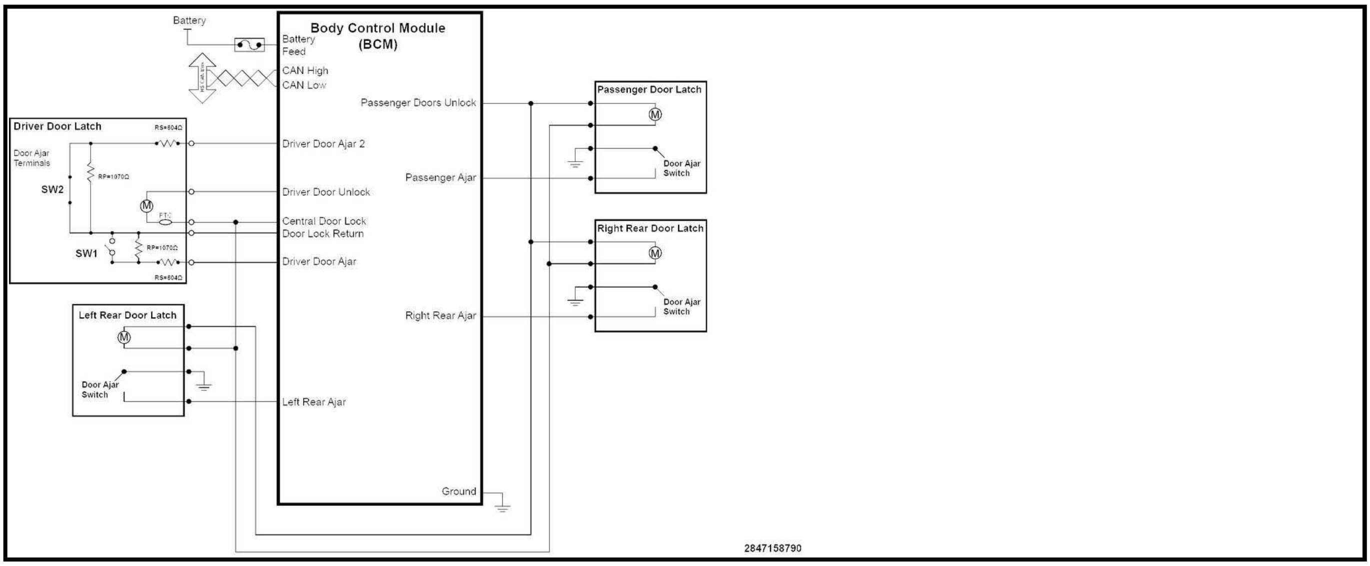
For a complete DOORS/LOCK SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Powertrain Control Module (PCM) receives the state (open/closed) of each switch over the CAN Bus from the Drivers Door Module (DDM) or Body Control Module (BCM) depending on the vehicles configuration and which module the latches are hard-wired to. The PCM continuously monitors the functioning status of the Driver Door Ajar Switch states for the operation of certain features such as Electric Stop/Start (ESS).

For further information on the effect of this DTC to the operation of ESS, see **ENGINE START/STOP (ESS) INOPERATIVE.** . Refer to ENGINE STOP/START (ESS) SYSTEM INOPERATIVE .

COMPONENT FUNCTIONAL DESCRIPTION - DOOR LATCH SYSTEM



Functional Operation of the Lock Motors: The Body Control Module (BCM) uses an H-Bridge configuration to drive the lock/unlock motors. To lock the doors, voltage is applied to the Lock pin circuit and ground is applied to both Unlock pin circuits. To unlock the doors, voltage is applied to the Unlock pins and ground is applied to the Lock pin. The passenger doors have a separate Unlock pin so that only the Driver's Door can be unlocked with the first button press on the keyless remote. When the lock motors are activated BCM will drive the motors for approximately 370 ms. The BCM and lock motors operate in the voltage range of 9.0 and 16.0 volts. Typical current draw for the motors are listed in Amps in the table below.

NOTE: **The amperage values listed in the table are approximate.**

BATTERY VOLTAGE	IN-RUSH CURRENT	CONTINUOUS OPERATION (NO LOAD)	STALL CURRENT
9.0	3.9	3.1	4.3
12.0	5.22	1.75	6.2
13.5	5.8	1.5	6.9
16.0	6.7	2.0	7.0

Functional Operation of the Latch Switches: All of the Door Latches are monitored to determine if they are closed or ajar. All of the ajar switches are wake-up signals to the BCM. The Driver Door Latch must be rationalized in order for some vehicle features to function. Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Door Ajar Switch signals use Battery voltage for a reference. The switches operate in the following manner:

- **Driver Door Ajar Switches:** The BCM has an internal pull up 1000 Ohm resistor for each ajar signal. Each switch has an internal 604 Ohm and 1070 Ohm resistor. When the switches are open the resistance through the switches are 1674 Ohms. When the switches are closed the resistance through the switches are 604 Ohms. The switch states are opposing each other, meaning that when the **door latch is closed** , switch 1 is in the open state and switch 2 is in the closed state. The opposite is true when the **door latch is opened** . For more information refer to the tables below.
- **Passenger Ajar Switches:** The ajar switches are open when the latch is closed. When the door latch is ajar the switch closes allowing the signal to connect to ground through the switch. Therefore the signal inputs to the BCM are high when the door is closed and low when the door is ajar.

The BCM monitors the Driver Door Ajar Switch signal circuit and converts the voltage signal into counts to broadcast over the CAN Bus network.

- Electronic Control Modules read an analog signal voltage and converts it to digital counts. Each count is an equal percentage of the signal reference voltage. This can be seen when viewing some sensor or switch voltages and converted values on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts to a battery voltage reference.
- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals are high resolution. This allows the module to read small changes over a wide range in a variable resistance sensor signal. These are typically used on a temperature, pressure, position or MUX type of sensor.
- Switches typically have a much lower resolution than sensors. This is because an ECU is generally looking for a switch to be in only a few positions that use fixed resistors. The lower resolution also helps the ECU to overcome some resistance in a circuit and still read the correct state. This also lowers the sensitivity to setting DTCs.
- The voltage and percentages can vary slightly with calibration changes. The voltage values and percentages in the table are approximate and can be slightly different. Typically, a failure will be noticeably different than the values in the table. The voltage ranges given are based on a nominal reference voltage of 13.5 volts. The voltage on the signal will change with system voltage but the percentage of system voltage should not change.

The Driver Door Ajar Switch signal voltage is divided into 15 counts typically. The table below shows the relation between the Driver Door Ajar Switch states and **approximate voltage percentages/ranges.**

DOOR AJAR SWITCH 1

VOLTAGE PERCENTAGE/VALUE TO SWITCH STATE			
Percentage of Battery Voltage	**Voltage Range @ 13.5 volts nominal**	**Door Latch Position**	**Ajar Switch State (Open/Closed)**
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	CLOSED	SWITCH OPEN
20 - 53%	Nominal: 4.5v Range: 2.7v- 6.3v	AJAR	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DOOR AJAR SWITCH 2

Percentage of Battery Voltage	Voltage Range @ 13.5 volts nominal	Door Latch Position	Ajar Switch State (Open/Closed)
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v	AJAR	SWITCH OPEN

Percentage of Battery Voltage	Voltage Range @ 13.5 volts nominal	Door Latch Position	Ajar Switch State (Open/Closed)
	Range: 7.2v - 9.9v		
20- 53%	Nominal: 4.5v Range: 2.7v- 6.3v	CLOSED	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DIAGNOSTIC OVERVIEW-DOOR LOCK MOTORS AND SWITCHES:

- **Lock Motors:** The BCM is capable of detecting opens and shorts in the H-Bridge control circuits. The locks are not thermally protected by the BCM. The protection is done by limiting the number of actuations within a calibrated time period.
- **Door Latch Switches:** The resistors in the latch switches allows the BCM to perform diagnostics on the circuits and switches. Unlike the passenger door switches the voltage on the two signals should not be high or low. If the BCM determines that either signal falls into the high or low range, a fault is set. If the door latch positions do not match between the two Driver Door Ajar Switches, a correlation fault will set.

WHEN MONITORED

- This diagnostic runs continuously with the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) receives the door ajar status over the CAN C BUS from the Body Control Module (BCM). The PCM detects that the Driver Door Latch Ajar Switch 2 state is stuck closed.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
LEFT FRONT DOOR LATCH WIRING ISSUE
LEFT FRONT DOOR LATCH ASSEMBLY
BODY CONTROL MODULE (BCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

- Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. Open and close the door several times.
    8. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

        Are there any Door Ajar Switch 2 circuit high or low faults present?

        Yes

        - Perform the applicable diagnostic procedure(s).

        No

        - Go To 4
4. **REPLACE THE LEFT FRONT DOOR LATCH ASSEMBLY AND RETEST FOR DTCS**
    1. Turn the ignition off.
    2. Replace the component (Door Latch) in accordance with the Service Information.
    3. Connect the component and Electronic Control Unit (ECU) harness connectors.
    4. Turn the ignition on.
    5. With the scan tool, erase all DTCs.
    6. Turn the ignition off for a minimum of 10.0 seconds.
    7. Turn the ignition on.
    8. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    9. Open and close the door several times.
    10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

- Go To 5

No

- Replacing the faulty component repaired the fault.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **CHECK RELATED BCM AND COMPONENT CONNECTIONS**
    1. Disconnect all BCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. With the scan tool, erase DTCs.
    9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    10. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Body Control Module (BCM) in accordance with the Service Information. Refer to **MODULE, BODY CONTROL (BCM), REMOVAL AND INSTALLATION** .
        - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

B25CB-DRIVER DOOR AJAR SWITCH 1/DRIVER DOOR AJAR SWITCH 2 CORRELATION

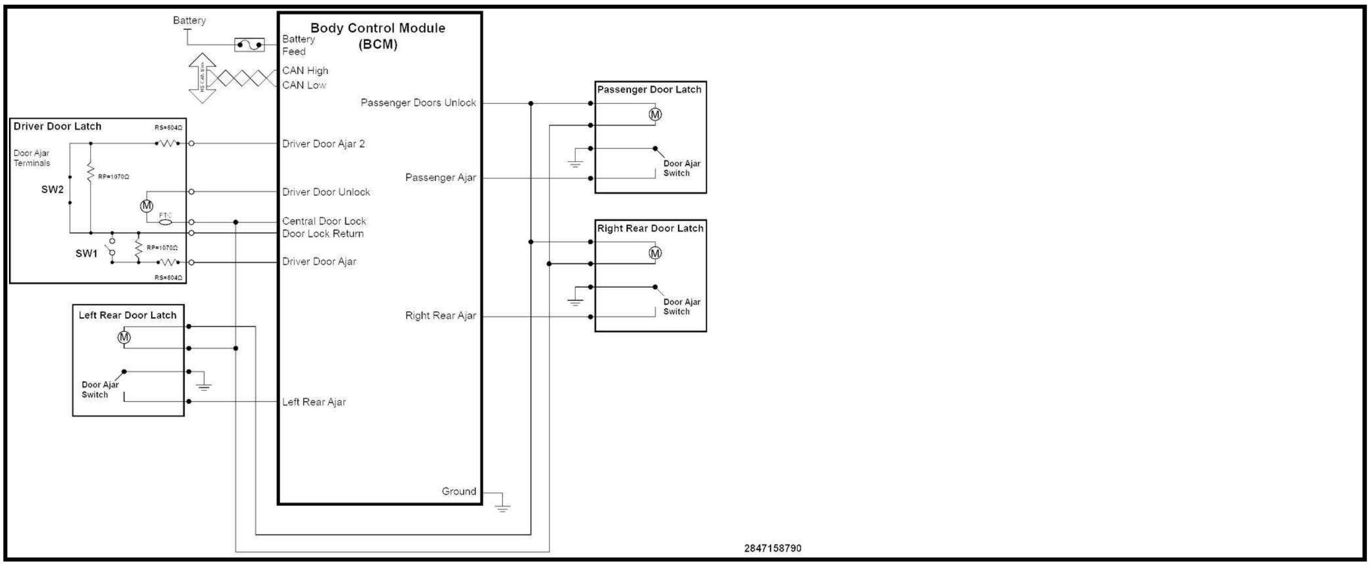
For a complete DOORS/LOCK SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Powertrain Control Module (PCM) receives the state (open/closed) of each switch over the CAN Bus from the Drivers Door Module (DDM) or Body Control Module (BCM) depending on the vehicles configuration and which module the latches are hard-wired to. The PCM continuously monitors the functioning status of the Driver Door Ajar Switch states for the operation of certain features such as Electric Stop/Start (ESS).

For further information on the effect of this DTC to the operation of ESS, see **ENGINE START/STOP (ESS) INOPERATIVE.** . Refer to ENGINE STOP/START (ESS) SYSTEM INOPERATIVE .

COMPONENT FUNCTIONAL DESCRIPTION - DOOR LATCH SYSTEM



Functional Operation of the Lock Motors: The Body Control Module (BCM) uses an H-Bridge configuration to drive the lock/unlock motors. To lock the doors, voltage is applied to the Lock pin circuit and ground is applied to both Unlock pin circuits. To unlock the doors, voltage is applied to the Unlock pins and ground is applied to the Lock pin. The passenger doors have a separate Unlock pin so that only the Driver's Door can be unlocked with the first button press on the keyless remote. When the lock motors are activated BCM will drive the motors for approximately 370 ms. The BCM and lock motors operate in the voltage range of 9.0 and 16.0 volts. Typical current draw for the motors are listed in Amps in the table below.

NOTE: **The amperage values listed in the table are approximate.**

BATTERY VOLTAGE	IN-RUSH CURRENT	CONTINUOUS OPERATION (NO LOAD)	STALL CURRENT
9.0	3.9	3.1	4.3
12.0	5.22	1.75	6.2
13.5	5.8	1.5	6.9
16.0	6.7	2.0	7.0

Functional Operation of the Latch Switches: All of the Door Latches are monitored to determine if they are closed or ajar. All of the ajar switches are wake-up signals to the BCM. The Driver Door Latch must be rationalized in order for some vehicle features to function. Unlike the passenger ajar signals that function like traditional open/closed ajar switches, the Driver Door Latch has redundant switches and signals for diagnostic purposes. The two switches share a common sensor ground. The Door Ajar Switch signals use Battery voltage for a reference. The switches operate in the following manner:

- **Driver Door Ajar Switches:** The BCM has an internal pull up 1000 Ohm resistor for each ajar signal. Each switch has an internal 604 Ohm and 1070 Ohm resistor. When the switches are open the resistance through the switches are 1674 Ohms. When the switches are closed the resistance through the switches are 604 Ohms. The switch states are opposing each other, meaning that when the **door latch is closed** , switch 1 is in the open state and switch 2 is in the closed state. The opposite is true when the **door latch is opened** . For more information refer to the tables below.
- **Passenger Ajar Switches:** The ajar switches are open when the latch is closed. When the door latch is ajar the switch closes allowing the signal to connect to ground through the switch. Therefore the signal inputs to the BCM are high when the door is closed and low when the door is ajar.

The BCM monitors the Driver Door Ajar Switch signal circuit and converts the voltage signal into counts to broadcast over the CAN Bus network.

- Electronic Control Modules read an analog signal voltage and converts it to digital counts. Each count is an equal percentage of the signal reference voltage. This can be seen when viewing some sensor or switch voltages and converted values on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts to a battery voltage reference.
- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals are high resolution. This allows the module to read small changes over a wide range in a variable resistance sensor signal. These are typically used on a temperature, pressure, position or MUX type of sensor.
- Switches typically have a much lower resolution than sensors. This is because an ECU is generally looking for a switch to be in only a few positions that use fixed resistors. The lower resolution also helps the ECU to overcome some resistance in a circuit and still read the correct state. This also lowers the sensitivity to setting DTCs.
- The voltage and percentages can vary slightly with calibration changes. The voltage values and percentages in the table are approximate and can be slightly different. Typically, a failure will be noticeably different than the values in the table. The voltage ranges given are based on a nominal reference voltage of 13.5 volts. The voltage on the signal will change with system voltage but the percentage of system voltage should not change.

The Driver Door Ajar Switch signal voltage is divided into 15 counts typically. The table below shows the relation between the Driver Door Ajar Switch states and **approximate voltage percentages/ranges.**

DOOR AJAR SWITCH 1

VOLTAGE PERCENTAGE/VALUE TO SWITCH STATE			
Percentage of Battery Voltage	**Voltage Range @ 13.5 volts nominal**	**Door Latch Position**	**Ajar Switch State (Open/Closed)**
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v Range: 7.2v - 9.9v	CLOSED	SWITCH OPEN
20 - 53%	Nominal: 4.5v Range: 2.7v- 6.3v	AJAR	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DOOR AJAR SWITCH 2

Percentage of Battery Voltage	**Voltage Range @ 13.5 volts nominal**	**Door Latch Position**	**Ajar Switch State (Open/Closed)**
87 - 100%	Range: 11.7v - 13.5v	-	CIRCUIT HIGH FAULT RANGE - OPEN CIRCUIT
54 - 86%	Nominal: 8.5v	AJAR	SWITCH OPEN

Percentage of Battery Voltage	Voltage Range @ 13.5 volts nominal	Door Latch Position	Ajar Switch State (Open/Closed)
	Range: 7.2v - 9.9v		
20- 53%	Nominal: 4.5v Range: 2.7v- 6.3v	CLOSED	SWITCH CLOSED
0 - 19%	Range: 0v - 1.8v	-	CIRCUIT LOW FAULT RANGE-SHORT TO GROUND

DIAGNOSTIC OVERVIEW-DOOR LOCK MOTORS AND SWITCHES:

- **Lock Motors:** The BCM is capable of detecting opens and shorts in the H-Bridge control circuits. The locks are not thermally protected by the BCM. The protection is done by limiting the number of actuations within a calibrated time period.
- **Door Latch Switches:** The resistors in the latch switches allows the BCM to perform diagnostics on the circuits and switches. Unlike the passenger door switches the voltage on the two signals should not be high or low. If the BCM determines that either signal falls into the high or low range, a fault is set. If the door latch positions do not match between the two Driver Door Ajar Switches, a correlation fault will set.

WHEN MONITORED

- With the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) receives a message over CAN C BUS from the Body Control Module (BCM) indicating that the Driver Door Ajar Switch states do not match.

DEFAULT ACTION

- This is a non-MIL fault.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
HIGH RESISTANCE IN THE DRIVER DOOR LATCH AJAR SWITCH SENSE CIRCUIT
HIGH RESISTANCE IN THE DRIVER DOOR LATCH AJAR SWITCH 2 SENSE CIRCUIT
DRIVER DOOR LATCH
BODY CONTROL MODULE (BCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (G75) AJAR SWITCH SENSE CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the ECU harness connector and measure the resistance of the circuit.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 4

    No

    - Repair the circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND CHECK THE DRIVER DOOR LATCH (G755) AJAR SWITCH 2 SENSE CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide

to follow the path of the circuit.
3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
5. Connect the other lead to the circuit being tested at the ECU harness connector and measure the resistance of the circuit.

Is the resistance below 3.0 Ohms?

Yes

- Go To 5

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **REPLACE THE DOOR LATCH AND RETEST FOR DTCS**
   1. Turn the ignition off.
   2. Replace the component in accordance with the Service Information. Refer to **LATCH, DOOR, REMOVAL AND INSTALLATION** .
   3. Connect the component and Electronic Control Unit (ECU) harness connectors.
   4. Turn the ignition on.
   5. With the scan tool, erase all DTCs.
   6. Turn the ignition off for a minimum of 10.0 seconds.
   7. Turn the ignition on.
   8. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
   9. Open and close the door several times.
   10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 6

No

- Replacing the faulty component repaired the fault.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK RELATED BCM AND COMPONENT CONNECTIONS**
   1. Disconnect all BCM harness connectors.
   2. Disconnect all related in-line harness connections (if equipped).
   3. Disconnect the related component harness connectors.
   4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Reconnect all BCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Body Control Module (BCM) in accordance with the Service Information. Refer to **MODULE, BODY CONTROL (BCM), REMOVAL AND INSTALLATION** .
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the BODY VERIFICATION TEST. Refer to **BODY VERIFICATION TEST** .

C0062-LONGITUDINAL ACCELERATION SENSOR

WHEN MONITORED

- This diagnostic runs continuously with the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) receives a message over the CAN BUS from the Anti-lock Brake System (ABS) Module that there is a fault with the Dynamic Sensor. The Dynamic Sensor is located within the Occupant Restraint Controller (ORC).

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
OCCUPANT RESTRAINT CONTROLLER (ORC)
ANTI-LOCK BRAKE SYSTEM (ABS) MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

CHECK FOR AN ACTIVE DTC

1. With the scan tool, read all DTCs and record on the repair order.

   Is the DTC active or pending?

   Yes

   - Refer to **ANTILOCK BRAKE SYSTEM (ABS) - DIAGNOSTIC CODE INDEX** and perform the appropriate diagnostic test.

   No

   - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

C0501-WHEEL SPEED SIGNAL LEFT FRONT RATIONALITY

For a complete BRAKE SYSTEM wiring diagram, **refer to the appropriate wiring information** .

DESCRIPTION AND OPERATION-BRAKING SYSTEMS

GENERAL NON-eBOOSTER BRAKING SYSTEM OPERATION: The Integrated Control Unit (ICU) consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The BSCM monitors the signal from the Brake Pedal Position (BPP) Sensor mounted on the Brake Pedal assembly and Master Cylinder Pressure (MCP) Sensor signal, mounted inside the HCU to detect when the Brake Pedal is applied. The BSCM also monitors the pressure sensors in each hydraulic circuit to calculate the Brake Torque signal. The calculation is based on the sum of pressure applied to the caliper in each hydraulic circuit. These signals are broadcast on the CAN bus. When the BSCM receives an autonomous brake input it controls a motor/actuator inside the Hydraulic Assembly to apply hydraulic pressure to the calipers to brake the vehicle.

GENERAL eBOOSTER BRAKING SYSTEM OPERATION: The Electronic Booster (eBooster) system consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The system does not use a conventional Master Cylinder mounted on the booster. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. To maintain normal Brake Pedal feel, when the Brake Pedal is pressed it creates hydraulic pressure in a fluid filled chamber inside the HCU. The pressure acts on a cap and spring inside the chamber allowing the pedal to get firm. This system uses a Brake Pedal Simulator Pressure Sensor in place of the MCP Sensor and two unique Brake Pedal Position (BPP) Sensors to monitor for an operator braking input. The BSCM monitors these and other inputs, and controls a motor/actuator inside the HCU to apply hydraulic pressure to the calipers during an operator braking input or autonomous braking event.

NOTE:	**If the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.**

WHEEL SPEED SENSOR OPERATION: Wheel Speed Sensors (WSS) are used to monitor vehicle speed and wheel slip conditions. The Wheel Speed Sensors are hard-wired to the Brake System Control Module. The BSCM broadcasts the WSS signals on the CAN bus. The BSCM performs circuit fault diagnostics for the WSS sensors and wiring. The BSCM and PCM perform rationality checks against the outputs from the sensors. **This is described in detail in the DIAGNOSTIC OVERVIEW information below.** The WSS signals are also compared to the Steering Wheel Angle and Dynamic Sensors. Comparing these signals together can determine when the vehicle is in a turning event or if there is a fault in one of the WSS signals.

ANTI-LOCK BRAKING EVENT: During a braking event, the BSCM monitors the WSS signals to detect a wheel lock condition due to a skid event. If a wheel is determined to be locked, the BSCM cycles the Outlet Valve. Cycling the valve off/on relieves and applies the pressure to the wheel to correct the condition. The pressure will be regulated until the wheel lock condition is no longer present.

TRACTION CONTROL AND ELECTRONIC STABILITY CONTROL (ESC): If a wheel spin condition is detected during driving, and the brakes are not being applied, the BSCM will cycle the Inlet Valve in the system, applying braking to the wheel to correct the wheel slip condition. The system monitors the steering wheel angle, yaw rate and lateral acceleration (Dynamic Sensor) and Wheel Speed Sensors to determine an over/under steer condition. The BSCM will open the appropriate Inlet Valves, applying braking to counteract the condition.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE PEDAL POSITION SENSOR

NON-eBOOSTER SYSTEMS: 3-Wire Position Sensor - The Non-eBooster systems use a single Brake Pedal Position Sensor mounted on the Brake Pedal assembly. The BSCM provides the sensor with a 5-Volt reference, a pull down signal and sensor ground circuit. Using a pull down signal means that there will be 0 volts on the signal circuit when the connector is unplugged. The sensor is hard-wired to the BSCM. The BSCM converts the analog voltage signal to a digital signal and broadcasts it on the CAN bus. When the pedal is not pressed, the signal voltage is low. As the driver presses on the Brake Pedal, the voltage on the signal increases. The Minimum (Not pressed) and maximum (Pedal fully pressed) thresholds for the sensors are learned into the BSCM and PCM. **These thresholds must be re-learned using the scan tool every time a sensor, BSCM or PCM is replaced. If these thresholds are not learned, a performance fault will set.**

eBOOSTER SYSTEMS: Single Edge Nibble Transmission (SENT) Sensors - The eBooster system uses two SENT interface protocol sensors used to detect brake pedal travel. These sensors are internal to the Hydraulic Control Unit assembly. As the driver presses on the Brake Pedal, the Brake Pedal Position Sensors send an output only digital signal to the BSCM in percentage of travel. These sensors consist of three circuits, a power supply and ground circuit to function, and a digital output signal circuit. The power supply range is typically between 4.75 and 5.25 volts.

COMPONENT FUNCTIONAL DESCRIPTION - HYDRAULIC CONTROL UNIT (HCU) ASSEMBLY

The HCU Assembly internal components are slightly different depending on the brake system. The functionality of applying the brakes is also different. During an Anti-lock braking, traction control or stability control event, the functionality of the systems is relatively the same.

- **NON-eBOOSTER SYSTEMS:** The HCU on this system incorporates a Master Cylinder Pressure (MCP) Sensor, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The Brake Pedal Position Sensor is external, but hard-wired to the BSCM. The BSCM in this system is capable of operating the motor/actuator inside the HCU to apply the brakes during an autonomous braking event. The vehicle operator can directly brake the vehicle by pressing on the Brake Pedal.
- **eBOOSTER SYSTEMS:** The HCU on this system incorporates a Brake Pedal Simulator Pressure Sensor, two Brake Pedal Position (BPP) Sensors, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The BSCM in this system operates the motor/actuator to apply the brakes during both vehicle operator input and autonomous braking events. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. However, if the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.

The Inlet Valves allow the fluid and hydraulic pressure to the calipers in each hydraulic circuit. The Outlet Valves are used to relieve the pressure in each circuit. There are two pressure sensors located in each hydraulic circuit that allow the BSCM to monitor the pressure in the system for each circuit.

COMPONENT FUNCTIONAL DESCRIPTION - WHEEL SPEED SENSORS

The Wheel Speed Sensors can be a magnetic pickup type or Hall Effect type sensor depending on the system being used. Each system uses a different type of target. The BSCM provides a signal voltage to the sensor and a ground path. The signal voltage can be 5v or 12v depending on the system.

- The system with magnetic pickup type sensors typically use a metal tone wheel that can be mounted on the hub/bearing assembly or front axle shaft. The tone wheel will have high and low spots equally spaced around the tone wheel. As the wheel is turning the high/low spots on the tone wheel pass the magnet in the sensor causing a square wave 5v or 12v signal.
- The system with Hall Effect sensors use a magnetic pole encoder that is typically incorporated in the wheel bearing assembly. With this system the air gap between the WSS and encoders is not adjustable. As the wheel is turning the magnets in the encoder pass the Hall Effect sensor causing a square wave 5v or 12v signal.

The PCM uses the Wheel Speed Sensor signals and Steering Angle Sensor signal for Engine Stop/Start enabling and oil aeration detection. The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the wheel speed signals are showing vehicle speed present, the PCM will disable ESS mode.
- If the vehicle is in a hard turning event, as determined by the wheel speed signals the oil can be dispersed to one side of the oil pan away from the pickup tube on some vehicles. This can cause oil aeration and affect the valve timing performance fault detection. During a hard turning event the valve timing performance diagnostics will be suspended until the event ends.

COMPONENT FUNCTIONAL DESCRIPTION - STEERING ANGLE SENSOR

Depending on the vehicle, the Steering Angle Sensor (SAS) can be mounted on the Steering Column, or incorporated into the Steering Column Control Module (SCCM) or Steering Gear. The SAS signal is broadcast on the CAN bus. The SAS signal is used by several modules to monitor the Steering Wheel position and rate of change for vehicle stability control, Engine Stop/Start enabling and autonomous operations.

The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the steering angle input is high (wheel turned) when the vehicle comes to a stop, and the vehicle is equipped with Electric Power Steering, the PCM will disable ESS mode. The Electric Power Steering can draw Battery voltage down quickly if the wheel is turned significantly and the engine is turned off.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE SYSTEM CONTROL MODULE (BSCM)

The BSCM is bolted to the Hydraulic Assembly. The BSCM monitors several inputs used for normal vehicle braking as well as detection and operation of anti-lock braking, traction, and electronic stability controls. The signals that are monitored are listed below. The BSCM directly monitors the signals for operating the:

- Brake Pedal Position Sensor(s)
- Master Cylinder Pressure Sensor (non-eBooster System)
- Brake Pedal Simulator Pressure Sensor (eBooster System)
- Hydraulic pressure sensors in each hydraulic circuit
- Wheel Speed Sensors
- Steering Angle Sensor
- Dynamic Sensor

These inputs are used to control the following output devices:

- Motor/actuator
- Hydraulic pump
- Inlet Check Valves

- Outlet Check Valves

TECHNICAL DATA-BRAKING SYSTEM MESSAGES

NON-eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM broadcasts the BPP Sensor signal voltage on the CAN bus. If the sensor signal is faulty, the BSCM sets a fault against the sensor and sends a Signal Not Available (SNA) message on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Master Cylinder Pressure Signal	Actual hydraulic pressure in the Master Cylinder	If the Master Cylinder Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends an SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Torque Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal is broadcast on the CAN bus.

eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM sends the average of the two BPP Sensor signal inputs on the CAN bus. If one sensor is faulted, the BSCM sets a fault against the sensor and sends the input from only the good sensor on the CAN bus. The PCM will function normally if only one sensor is faulty. If both sensors are faulty, the BSCM sets a fault against both sensors and sends a Signal Not Available (SNA) signal on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Brake Pedal Pressure Signal	Simulated Brake Pedal applied pressure	If the Brake Pedal Simulator Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends and SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Boost Pressure Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal broadcast on the CAN bus.
BSCM Readiness Flag	Informs PCM that ESS can be performed.	The BSCM sends an ESS readiness flag (TRUE) message when the BSCM

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
		determines that ESS can be enabled. This is based on hydraulic pressure to the calipers and road grade calculation.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

Performance Faults (P057B/C053D/C10F5):

- With the ignition on.
- Battery voltage above 10.4 volts.
- No Loss of Communication or implausible/missing message faults active.

Communication Faults (U0121/U0129/U0418/U11BF):

- With the ignition on.
- Battery voltage above 10.4 volts.

Wheel Speed Sensor Signal and Distance Faults (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418):

- With the ignition on.
- Battery voltage between 9.0 and 16.0 volts.

SET CONDITION

- **C053D** - The PCM determines that the Master Cylinder Pressure Sensor signal is irrational.
- **C10F5** - The PCM determines that the Brake Torque signal is irrational.
- **P057B** - The PCM determines that the Brake Pedal Position Sensor signal is irrational.
- **U0121** - The PCM does not receive the Brake Pedal Position Sensor signal.
- **U0129** - The PCM does not receive the Master Cylinder Pressure Sensor signal.
- **U0418** - The PCM receives an SNA message indicating that the has detected a fault in the Master Cylinder Pressure Sensor signal.
- **U11BF** - The PCM receives an SNA message indicating that the has detected a fault in the Brake Pedal Position Sensor signal.
- **(C0501, C0507, C050D, C0513) Wheel Speed Signal Rationality Faults** - When at a stop, one WSS signal is showing vehicles speed output and the other three WSS signals are reading 0 OR When the difference between one WSS signal compared to the other three WSS signals is more than 11 MPH, for 30 seconds.
- **(U1409, U140A, U140B, U140C, U1412, U1417, U1418) Implausible Wheel Speed and Distance Signal Faults** - These faults will typically set when the BSCM detects a fault with one of the WSS signals. The BSCM will send an SNA or error flag against the sensor.

The (P057B, P057C, P057D, U11BF) BPP Sensor faults can set for any of the following:

DEFAULT ACTION

- The MIL will illuminate.
- ESS System is disabled.

POSSIBLE CAUSES

POSSIBLE CAUSES
5-VOLT SUPPLY CIRCUIT OPEN OR SHORTED TO GROUND
BPP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH)
BPP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW)
BPP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
BPP SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
FAULTY BRAKE PEDAL POSITION SENSOR
FAULTY BRAKE SYSTEM MODULE (BSM)

The (C053D, C10F5, U0418) performance and implausible/lost message faults can set for any of the following:

POSSIBLE CAUSES
FAULTY HYDRAULIC ASSEMBLY (BPP AND BRAKE SIMULATOR SENSORS ARE INTERNAL)
FAULTY BRAKE SYSTEM MODULE (BSM)

The (U0121, U0129) Loss of Communication faults can set for any of the following:

POSSIBLE CAUSES
BATTERY OR IGNITION SUPPLY TO BSM OPEN OR SHORTED TO GROUND
BSM GROUND CIRCUIT OPEN/HIGH RESISTANCE
BSM CAN BUS CIRCUITS SHORTED TO VOLTAGE
BSM CAN BUS CIRCUITS SHORTED TO GROUND
BSM CAN BUS CIRCUITS OPEN/HIGH RESISTANCE
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

The Wheel Speed Sensor faults can set for any of the following:

POSSIBLE CAUSES
SNA OR ERROR MESSAGE FROM BSCM
WSS SIGNAL CIRCUITS SHORTED TO VOLTAGE
WSS SIGNAL CIRCUITS SHORTED TO GROUND
WSS SIGNAL CIRCUITS OPEN/HIGH RESISTANCE
WSS GROUND CIRCUIT OPEN/HIGH RESISTANCE
DAMAGED TONE WHEEL
FAULTY WHEEL SPEED SENSOR
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

DIAGNOSTIC OVERVIEW

NON-eBOOSTER SYSTEM: When any faults are present against the BPP Sensor in the BSCM or PCM, the sensor and circuits should always be checked before condemning a module. While the Master Cylinder Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an ICU assembly.

eBOOSTER SYSTEM: While the BPP Sensors, Brake Pedal Simulator Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an eBooster assembly.

WHEEL SPEED SENSORS: When the vehicle is moving, the Wheel Speed Sensor signals are rationalized against each other for a stuck sensor. The controller is able to determine difference between a fault and a normal vehicle turning event (explained below).

WHEEL SPEED SENSOR COMPARISONS MONITORED	
Left Front vs Right Front	LF/RF
Left Front vs Left Rear	LF/LR
Left Front vs Right Rear	LF/RR
Right Front vs Left Rear	RF/LR
Right Front vs Right Rear	RF/RR
Left Rear vs Right Rear	LR/RR

The **enable condition threshold** is used as the comparison threshold. The threshold is calculated by taking the average of the six comparison calculations in the table when the vehicle is moving.

- **Driving Straight** - When the vehicle is moving in a straight line (steering wheel angle is near zero) the four sensor signal outputs should be relatively equal. If the LF sensor was stuck, the difference in the three calculations between the LF and other three sensors (LF/RF, LF/LR, LF/RR) will be above the enable condition threshold and the other three calculations (RF/LR, RF/RR, LR/RR) will be below the enable condition threshold, indicating a LF Wheel Speed Sensor failure.
- **Turning** - When the vehicle is turning all of the comparison checks will be different. The differences for all of the comparison checks will increase as the turning radius increases. If all comparison checks are above the calculated enable condition threshold, the vehicle is considered to be in a significant turning event and the diagnostic is temporarily disabled.
- **Vehicle Stopped** - When the vehicle is stopped each Wheel Speed Sensor signal should be 0. If three sensor outputs equal 0 and the forth is above 0 for a calibrated period threshold, the sensor is determined to be irrational.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.
2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connection issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways.

Check the Battery or Batteries for proper charge and operation along with proper connections. Use the appropriate wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.

4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

DIAGNOSTIC TEST - NON-EBOOSTER BRAKE SYSTEM - PCM

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

BRAKE PEDAL POSITION SENSOR CIRCUIT FAULTS (P057C, P057D): TECH TIP: Typical three wire sensors must have voltage present on the 5-Volt Supply circuit to function properly. No voltage on the 5-Volt Supply circuit can cause the sensor to react one of two ways, depending on the type of sensor being used. The first is the sensor signal voltage can be stuck mid range (2.4-2.6 volts), and not change which can cause a performance fault. The second is the signal voltage can be stuck low (0 volts) since the ECU is using a pull-down signal.

1. Check the sensor harness connector for proper connection at the BPP Sensor. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the BPP Sensor harness connector and check for any pushed out, damaged, corroded or spread terminals.
2. Measure the voltage on the 5-Volt Supply circuit with the ignition on. The voltage should measure above 4.9 volts.
    1. If voltage is present, continue to step 3.
    2. If no voltage is present at the harness connector, repair the 5-Volt Supply circuit for an open or high resistance.
3. This step is designed to determine if the fault is being caused by a faulty sensor. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the BPP Sensor signal and 5-Volt Supply circuit at the BPP Sensor harness connector. A fused jumper can also be used for this step. Move the switch on the Electrical Test Lead Kit to the CLOSED position while either monitoring the voltage or fault screen on the scan tool. The voltage should read 5.0v if available, or the circuit high fault should be active. Next, connect the leads between the signal circuit and the sensor circuit at the BPP Sensor harness connector. The voltage should read 0v if available, or the circuit low fault should be active.

NOTE: **Since the BSCM uses a pull down signal, simply disconnecting the sensor harness connector should also give the same results.**

    1. If the voltage or faults appear as described above, the BPP Sensor is most likely faulty.
    2. If the voltage remains at 0v and only the circuit low fault is active, continue to step 4.
4. Disconnect the BSCM harness connector to isolate the circuits and check the sensor signal circuit for continuity to both chassis ground and the sensor ground circuit.
    1. If there is continuity to either, repair the signal circuit for a short to chassis ground or the sensor ground circuit.
    2. If the signal circuit is not shorted, continue to step 5.
5. Measure the resistance of the sensor signal and sensor ground circuits. Typically the circuit resistance should be less than 5.0 Ohms.
    1. If there is an open or high resistance in either circuit, repair the signal circuit for an open or high resistance.
    2. If the temp sensor signal and ground circuits test good, Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning BSCM. If no issues are found, replace the BSCM in accordance with the service information.

PCM SYSTEM PERFORMANCE FAULTS (P057B, C053D, C10F5): The signal performance faults set when one of the following signals received from the BSCM is irrational when compared to the others. The rationality checks are only done during a driver initiated braking event, not during an autonomous braking event.

- P057B - Brake Pedal Position signal is irrational.
- C053D - Master Cylinder Pressure signal is irrational.
- C10F5 - Brake Torque signal is irrational.

The Master Cylinder Pressure Sensor is internal to the Hydraulic Control Unit (HCU). The Brake Torque signal is calculated by the BSCM. The calculation is based on the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. If one of these signals is irrational, the HCU or BSCM are likely faulty.

1. If the P057B fault is present, perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).

- If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
- If the BSCM and terminals appear good, replace the eBooster assembly in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM IMPLAUSIBLE DATA FAULT (U11BF): The lost brake signal fault sets when the BSCM detects a fault against the Brake Pedal Pressure Sensor and has no rational signal to send to the PCM.

1. There should be a circuit fault set in the PCM, BSCM or both. Perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
   - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
   - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM IMPLAUSIBLE DATA FAULT (U0418): The implausible data fault sets when the BSCM detects a fault against the Master Cylinder Pressure Sensor and has no rational signal to send to the PCM.

1. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
   - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
   - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM LOSS OF COMMUNICATION FAULTS (U0121, U0129): The U0121 fault sets when the PCM does not receive the Brake Pedal Position Sensor signal message from the BSCM and the U0129 fault sets when the PCM does not receive the Master Cylinder Pressure Sensor signal message. Perform the following diagnostic checks for the Brake System Control Module:

1. Check for any Service Bulletins, Star On-line Cases, PCM or BSCM flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause a DTC.
3. Verify the vehicle modules are configured correctly. An incorrect configuration can cause a Loss of Communication fault.

4. Using the wiring information as a guide, check the fuse or fuses that supply power to BSCM. Verify the fuse(s) are not open and has a good connection with the terminals in the PDC
   1. If the fuse(s) are good, continue testing in step 5.
   2. If a fuse is open, check the supply circuit for a short to ground before replacing the fuse.
5. 
   Disconnect the BSCM harness connector and load test the Battery Supply and Ignition circuits.

   1. A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to **CIRCUIT LOAD TESTING PROCEDURES** .
   2. To verify that there is no resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. The voltage drop across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.
      - If either circuit fails the load testing, repair the resistance in the circuit. If the fuse that supplies power to the module is open or damaged
      - If both circuits pass the load test, continue testing in step 6.
6. 
   Load test the BSCM Ground circuit.

   1. If the ground circuit fails load testing, repair the BSCM chassis ground.
   2. If the ground circuit tests good, continue testing in step 7.
7. Check the voltage on the CAN Bus (+) and CAN Bus (-) circuits at the BSCM. Typically the CAN Bus (+) voltage should be approximately 2.6v and CAN Bus (-) voltage should be approximately 2.4v.
   1. If the voltage readings do not match the values given above, check the suspect circuit for opens or shorts.

NOTE: **A short in a Bus circuit would likely cause a Bus Performance fault or affect several modules. If only one module has Loss of Communication faults logged against it due to a wiring issue, it would likely be due to an open in a Bus circuit in the module harness connector or the wiring leading to that module.**

2. If both voltage readings match the values given, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the BSCM. To check for an intermittent condition, connect a lab scope to both circuits at the BSCM connector and wiggle test to the wiring harnesses monitoring for a drop in either Bus circuit. If no issues are found, replace the BSCM in accordance with the service information.

The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

DIAGNOSTIC TEST-WHEEL SPEED SENSOR FAULTS

PCM RELATED WHEEL SPEED SENSOR SIGNAL FAULTS (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418)

BSCM RELATED WHEEL SPEED SENSOR FAULTS - The BSCM performs the following diagnostic checks on the Wheel Speed Sensors

- Signal circuit continuity check (C0031-1D, C0034-1D, C0036-1D, C0037-1D)
- Erratic signal check (C0031-2F, C0034-2F, C0036-2F, C0037-2F)
- Incorrect component installed check - (C0031-4A, C0034-4A, C0036-4A, C0037-4A) - front and rear sensors are not compatible on some vehicles.
- Rationality check (C0031-62, C0034-62, C0036-62, C0037-62)

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

DIAGNOSING AN INCORRECT COMPONENT INSTALLED FAULT IN BSCM (C0031-4A, C0034-4A, C0036-4A, C0037-4A):

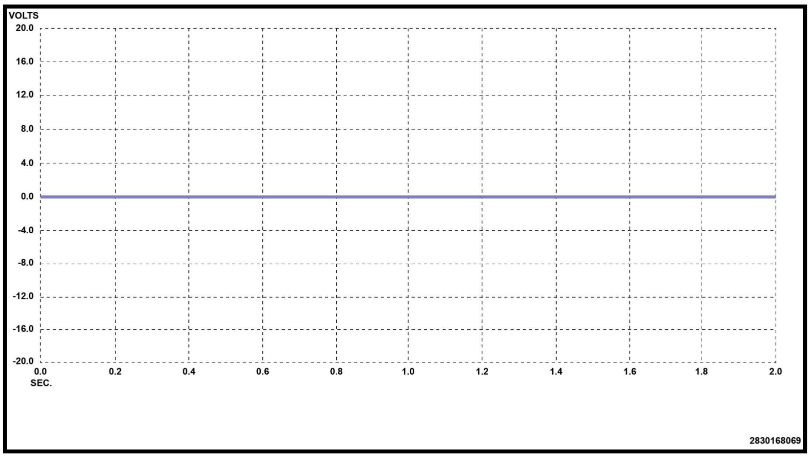
1. Some vehicles use a non-directional front WSS and directional rear WSS. The sensors are not interchangeable. Verify the correct WSS is installed on the vehicle for this fault.
   1. If the wrong part is installed, replace the WSS with the correct part number and verify repair.
   2. If the correct part is installed, replace the WSS. Clear the DTC, test drive the vehicle and confirm repair. If the DTC returns replace the Brake System Control Module in accordance with the Service Information.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A LAB SCOPE - PREFERRED METHOD (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

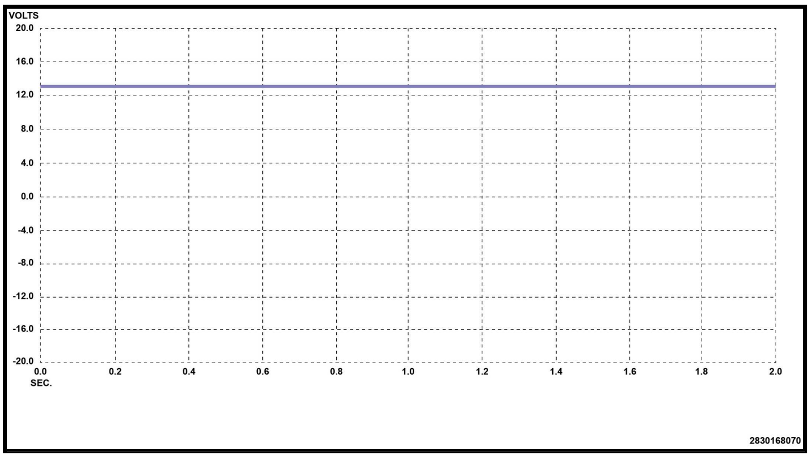
1. Turn the ignition on. At the WSS harness connector, back probe the WSS signal circuit with the lab scope test lead. The harness connector should be plugged into the WSS. Raise the vehicle on a hoist and turn the wheel while monitoring the scope signal. There should be a consistent square wave signal cycling between 0v and some voltage. The voltage may vary depending on the vehicle. The frequency of the

signal will change with the speed of the wheel but the consistency of the pattern should not. While turning the wheel watch the signal closely for the following. Inconsistency in the signal (gaps too large or small) due to a defective tone wheel/encoder or a loose, damaged sensor. A signal that is stuck high or stuck low. A signal that falls off intermittently or at lower speeds. Pick the scenario that best matches the results.

1. **The square wave signal is consistently cycling** - the sensor signal is giving a legitimate reading. The WSS and wiring are performing properly. Test drive the vehicle while monitoring the sensors. If the signal is erratic or dropping off during the test drive, check the sensor, wheel bearing and hub for looseness or damage that may not be showing up on the hoist. If the sensor reads correctly during the test drive and the fault is active, the BSCM is likely faulty. Always check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.
2. **The square wave signal is cycling but has erratic gaps or periodically drops off** - All of the issues listed can cause an erratic signal.
   - Check the WSS for physical damage and verify it is mounted and fastened properly.
   - If equipped with a tone wheel, inspect the tone wheel for physical damage.
   - On vehicles with encoders check the wheel bearing and hub for a worn bearing or excessive runout.
   - If no damage is found in the WSS, tone wheel, hub or wheel bearing assembly, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent circuit issue. If no issues are found, replace the Wheel Speed Sensor and verify repair.
3. **The signal has a constant 0.0 volt reading** - this indicates that the WSS Signal circuit is shorted to ground or has an open between the BSCM and WSS. Disconnect the WSS and BSCM harness connectors. Check the WSS Signal circuit for high resistance or a short to ground. If the WSS Signal circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.



4. **The signal reading has a constant voltage** - this indicates an open further downstream in the circuitry. Most likely the WSS or the Sensor Ground circuit. Continue testing in step 2.



2. To check the WSS, back probe and attach a scope lead to the Sensor Ground circuit at the WSS harness connector.
    1. **If the Sensor Ground circuit voltage is reading a constant 0.0 volts** - this would indicate an open in, or short across the WSS. The WSS is the faulty.
    2. **If the Sensor Ground circuit has a constant voltage** - this indicates an open in the Sensor Ground circuit path. Disconnect the WSS and BSCM harness connectors. Check the Sensor Ground circuit for high resistance. If the Sensor Ground circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A DVOM (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

1. Check the WSS harness connector for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the WSS harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.
2. Turn the ignition on and measure the voltage across the WSS (+) and WSS (-) circuits at the WSS harness connector. If both circuits are good there should be voltage present.
    1. If the voltage reads above 10.0 volts, the BSCM and circuits are testing good. Wiggle test the wiring while monitoring the voltage to check for an intermittent connection. If the voltage is steady above 10.0 volts, the Wheel Speed Sensor is likely faulty. Replace the Wheel Speed Sensor and verify repair.
    2. If no voltage is present, continue testing in step 3.
3. Remove the DVOM test lead from the WSS (-) circuit and connect to a good chassis ground. Measure the voltage on the WSS (+) circuit.
    1. If the voltage reads above 10.0 volts with the DVOM connected to chassis ground, the WSS (-) circuit is likely open or has high resistance between the WSS and the BSCM. If the circuit tests good (no resistance), the BSCM internal ground is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
    2. If no voltage is present on the WSS (+) circuit with the DVOM connected to chassis ground, continue testing in step 4.
4. Turn the ignition off and disconnect the BSCM harness connector. Check the WSS (+) circuit for continuity to both chassis ground and the WSS (-) circuit at the WSS harness connector.
    1. If there is continuity to either, repair the WSS (+) circuit for a short to ground or the WSS (-) circuit.
    2. If the signal circuit is not shorted, continue testing in step 5.
5. Measure the resistance of the WSS (+) circuit between the WSS harness connector and BSCM harness connector. There should be less than 3.0 Ohms of resistance.

1. If the resistance is below 3.0 Ohms, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
2. If the resistance is above 3.0 Ohms, repair the WSS (+) circuit for an open or high resistance.

C0507-WHEEL SPEED SIGNAL RIGHT FRONT RATIONALITY

For a complete BRAKE SYSTEM wiring diagram, **refer to the appropriate wiring information** .

DESCRIPTION AND OPERATION-BRAKING SYSTEMS

GENERAL NON-eBOOSTER BRAKING SYSTEM OPERATION: The Integrated Control Unit (ICU) consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The BSCM monitors the signal from the Brake Pedal Position (BPP) Sensor mounted on the Brake Pedal assembly and Master Cylinder Pressure (MCP) Sensor signal, mounted inside the HCU to detect when the Brake Pedal is applied. The BSCM also monitors the pressure sensors in each hydraulic circuit to calculate the Brake Torque signal. The calculation is based on the sum of pressure applied to the caliper in each hydraulic circuit. These signals are broadcast on the CAN bus. When the BSCM receives an autonomous brake input it controls a motor/actuator inside the Hydraulic Assembly to apply hydraulic pressure to the calipers to brake the vehicle.

GENERAL eBOOSTER BRAKING SYSTEM OPERATION: The Electronic Booster (eBooster) system consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The system does not use a conventional Master Cylinder mounted on the booster. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. To maintain normal Brake Pedal feel, when the Brake Pedal is pressed it creates hydraulic pressure in a fluid filled chamber inside the HCU. The pressure acts on a cap and spring inside the chamber allowing the pedal to get firm. This system uses a Brake Pedal Simulator Pressure Sensor in place of the MCP Sensor and two unique Brake Pedal Position (BPP) Sensors to monitor for an operator braking input. The BSCM monitors these and other inputs, and controls a motor/actuator inside the HCU to apply hydraulic pressure to the calipers during an operator braking input or autonomous braking event.

NOTE: **If the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.**

WHEEL SPEED SENSOR OPERATION: Wheel Speed Sensors (WSS) are used to monitor vehicle speed and wheel slip conditions. The Wheel Speed Sensors are hard-wired to the Brake System Control Module. The BSCM broadcasts the WSS signals on the CAN bus. The BSCM performs circuit fault diagnostics for the WSS sensors and wiring. The BSCM and PCM perform rationality checks against the outputs from the sensors. **This is described in detail in the DIAGNOSTIC OVERVIEW information below.** The WSS signals are also compared to the Steering Wheel Angle and Dynamic Sensors. Comparing these signals together can determine when the vehicle is in a turning event or if there is a fault in one of the WSS signals.

ANTI-LOCK BRAKING EVENT: During a braking event, the BSCM monitors the WSS signals to detect a wheel lock condition due to a skid event. If a wheel is determined to be locked, the BSCM cycles the Outlet Valve. Cycling the valve off/on relieves and applies the pressure to the wheel to correct the condition. The pressure will be regulated until the wheel lock condition is no longer present.

TRACTION CONTROL AND ELECTRONIC STABILITY CONTROL (ESC): If a wheel spin condition is detected during driving, and the brakes are not being applied, the BSCM will cycle the Inlet Valve in the system, applying braking to the wheel to correct the wheel slip condition. The system monitors the steering wheel angle, yaw rate and lateral acceleration (Dynamic Sensor) and Wheel Speed Sensors to determine an over/under steer condition. The BSCM will open the appropriate Inlet Valves, applying braking to counteract the condition.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE PEDAL POSITION SENSOR

NON-eBOOSTER SYSTEMS: 3-Wire Position Sensor - The Non-eBooster systems use a single Brake Pedal Position Sensor mounted on the Brake Pedal assembly. The BSCM provides the sensor with a 5-Volt reference, a pull down signal and sensor ground circuit. Using a pull down signal means that there will be 0 volts on the signal circuit when the connector is unplugged. The sensor is hard-wired to the BSCM. The BSCM converts the analog voltage signal to a digital signal and broadcasts it on the CAN bus. When the pedal is not pressed, the signal voltage is low. As the driver presses on the Brake Pedal, the voltage on the signal increases. The Minimum (Not pressed) and maximum (Pedal fully pressed) thresholds for the sensors are learned into the BSCM and PCM. **These thresholds must be re-learned using the scan tool every time a sensor, BSCM or PCM is replaced. If these thresholds are not learned, a performance fault will set.**

eBOOSTER SYSTEMS: Single Edge Nibble Transmission (SENT) Sensors - The eBooster system uses two SENT interface protocol sensors used to detect brake pedal travel. These sensors are internal to the Hydraulic Control Unit assembly. As the driver presses on the Brake Pedal, the Brake Pedal Position Sensors send an output only digital signal to the BSCM in percentage of travel. These sensors consist of three circuits, a power supply and ground circuit to function, and a digital output signal circuit. The power supply range is typically between 4.75 and 5.25 volts.

COMPONENT FUNCTIONAL DESCRIPTION - HYDRAULIC CONTROL UNIT (HCU) ASSEMBLY

The HCU Assembly internal components are slightly different depending on the brake system. The functionality of applying the brakes is also different. During an Anti-lock braking, traction control or stability control event, the functionality of the systems is relatively the same.

- **NON-eBOOSTER SYSTEMS:** The HCU on this system incorporates a Master Cylinder Pressure (MCP) Sensor, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The Brake Pedal Position Sensor is external, but hard-wired to the BSCM. The BSCM in this system is capable of operating the motor/actuator inside the HCU to apply the brakes during an autonomous braking event. The vehicle operator can directly brake the vehicle by pressing on the Brake Pedal.

- **eBOOSTER SYSTEMS:** The HCU on this system incorporates a Brake Pedal Simulator Pressure Sensor, two Brake Pedal Position (BPP) Sensors, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The BSCM in this system operates the motor/actuator to apply the brakes during both vehicle operator input and autonomous braking events. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. However, if the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.

The Inlet Valves allow the fluid and hydraulic pressure to the calipers in each hydraulic circuit. The Outlet Valves are used to relieve the pressure in each circuit. There are two pressure sensors located in each hydraulic circuit that allow the BSCM to monitor the pressure in the system for each circuit.

COMPONENT FUNCTIONAL DESCRIPTION - WHEEL SPEED SENSORS

The Wheel Speed Sensors can be a magnetic pickup type or Hall Effect type sensor depending on the system being used. Each system uses a different type of target. The BSCM provides a signal voltage to the sensor and a ground path. The signal voltage can be 5v or 12v depending on the system.

- The system with magnetic pickup type sensors typically use a metal tone wheel that can be mounted on the hub/bearing assembly or front axle shaft. The tone wheel will have high and low spots equally spaced around the tone wheel. As the wheel is turning the high/low spots on the tone wheel pass the magnet in the sensor causing a square wave 5v or 12v signal.
- The system with Hall Effect sensors use a magnetic pole encoder that is typically incorporated in the wheel bearing assembly. With this system the air gap between the WSS and encoders is not adjustable. As the wheel is turning the magnets in the encoder pass the Hall Effect sensor causing a square wave 5v or 12v signal.

The PCM uses the Wheel Speed Sensor signals and Steering Angle Sensor signal for Engine Stop/Start enabling and oil aeration detection. The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the wheel speed signals are showing vehicle speed present, the PCM will disable ESS mode.
- If the vehicle is in a hard turning event, as determined by the wheel speed signals the oil can be dispersed to one side of the oil pan away from the pickup tube on some vehicles. This can cause oil aeration and affect the valve timing performance fault detection. During a hard turning event the valve timing performance diagnostics will be suspended until the event ends.

COMPONENT FUNCTIONAL DESCRIPTION - STEERING ANGLE SENSOR

Depending on the vehicle, the Steering Angle Sensor (SAS) can be mounted on the Steering Column, or incorporated into the Steering Column Control Module (SCCM) or Steering Gear. The SAS signal is broadcast on the CAN bus. The SAS signal is used by several modules to monitor the Steering Wheel position and rate of change for vehicle stability control, Engine Stop/Start enabling and autonomous operations.

The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the steering angle input is high (wheel turned) when the vehicle comes to a stop, and the vehicle is equipped with Electric Power Steering, the PCM will disable ESS mode. The Electric Power Steering can draw Battery voltage down quickly if the wheel is turned significantly and the engine is turned off.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE SYSTEM CONTROL MODULE (BSCM)

The BSCM is bolted to the Hydraulic Assembly. The BSCM monitors several inputs used for normal vehicle braking as well as detection and operation of anti-lock braking, traction, and electronic stability controls. The signals that are monitored are listed below. The BSCM directly monitors the signals for operating the:

- Brake Pedal Position Sensor(s)
- Master Cylinder Pressure Sensor (non-eBooster System)
- Brake Pedal Simulator Pressure Sensor (eBooster System)
- Hydraulic pressure sensors in each hydraulic circuit
- Wheel Speed Sensors
- Steering Angle Sensor
- Dynamic Sensor

These inputs are used to control the following output devices:

- Motor/actuator
- Hydraulic pump
- Inlet Check Valves
- Outlet Check Valves

TECHNICAL DATA-BRAKING SYSTEM MESSAGES

NON-eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM broadcasts the BPP Sensor signal voltage on the CAN bus. If the sensor signal is faulty, the BSCM sets a fault against the sensor and sends a Signal Not Available (SNA) message

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
		on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Master Cylinder Pressure Signal	Actual hydraulic pressure in the Master Cylinder	If the Master Cylinder Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends an SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Torque Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal is broadcast on the CAN bus.

eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM sends the average of the two BPP Sensor signal inputs on the CAN bus. If one sensor is faulted, the BSCM sets a fault against the sensor and sends the input from only the good sensor on the CAN bus. The PCM will function normally if only one sensor is faulty. If both sensors are faulty, the BSCM sets a fault against both sensors and sends a Signal Not Available (SNA) signal on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Brake Pedal Pressure Signal	Simulated Brake Pedal applied pressure	If the Brake Pedal Simulator Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends and SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Boost Pressure Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal broadcast on the CAN bus.
BSCM Readiness Flag	Informs PCM that ESS can be performed.	The BSCM sends an ESS readiness flag (TRUE) message when the BSCM determines that ESS can be enabled. This is based on hydraulic pressure to the calipers and road grade calculation.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

Performance Faults (P057B/C053D/C10F5):

- With the ignition on.
- Battery voltage above 10.4 volts.

- No Loss of Communication or implausible/missing message faults active.

Communication Faults (U0121/U0129/U0418/U11BF):

- With the ignition on.
- Battery voltage above 10.4 volts.

Wheel Speed Sensor Signal and Distance Faults (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418):

- With the ignition on.
- Battery voltage between 9.0 and 16.0 volts.

SET CONDITION

- **C053D** - The PCM determines that the Master Cylinder Pressure Sensor signal is irrational.
- **C10F5** - The PCM determines that the Brake Torque signal is irrational.
- **P057B** - The PCM determines that the Brake Pedal Position Sensor signal is irrational.
- **U0121** - The PCM does not receive the Brake Pedal Position Sensor signal.
- **U0129** - The PCM does not receive the Master Cylinder Pressure Sensor signal.
- **U0418** - The PCM receives an SNA message indicating that the has detected a fault in the Master Cylinder Pressure Sensor signal.
- **U11BF** - The PCM receives an SNA message indicating that the has detected a fault in the Brake Pedal Position Sensor signal.
- **(C0501, C0507, C050D, C0513) Wheel Speed Signal Rationality Faults** - When at a stop, one WSS signal is showing vehicles speed output and the other three WSS signals are reading 0 OR When the difference between one WSS signal compared to the other three WSS signals is more than 11 MPH, for 30 seconds.
- **(U1409, U140A, U140B, U140C, U1412, U1417, U1418) Implausible Wheel Speed and Distance Signal Faults** - These faults will typically set when the BSCM detects a fault with one of the WSS signals. The BSCM will send an SNA or error flag against the sensor.

The (P057B, P057C, P057D, U11BF) BPP Sensor faults can set for any of the following:

DEFAULT ACTION

- The MIL will illuminate.
- ESS System is disabled.

POSSIBLE CAUSES

POSSIBLE CAUSES
5-VOLT SUPPLY CIRCUIT OPEN OR SHORTED TO GROUND
BPP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH)
BPP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW)
BPP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
BPP SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
FAULTY BRAKE PEDAL POSITION SENSOR
FAULTY BRAKE SYSTEM MODULE (BSM)

The (C053D, C10F5, U0418) performance and implausible/lost message faults can set for any of the following:

POSSIBLE CAUSES
FAULTY HYDRAULIC ASSEMBLY (BPP AND BRAKE SIMULATOR SENSORS ARE INTERNAL)
FAULTY BRAKE SYSTEM MODULE (BSM)

The (U0121, U0129) Loss of Communication faults can set for any of the following:

POSSIBLE CAUSES
BATTERY OR IGNITION SUPPLY TO BSM OPEN OR SHORTED TO GROUND
BSM GROUND CIRCUIT OPEN/HIGH RESISTANCE
BSM CAN BUS CIRCUITS SHORTED TO VOLTAGE
BSM CAN BUS CIRCUITS SHORTED TO GROUND
BSM CAN BUS CIRCUITS OPEN/HIGH RESISTANCE
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

The Wheel Speed Sensor faults can set for any of the following:

POSSIBLE CAUSES
SNA OR ERROR MESSAGE FROM BSCM
WSS SIGNAL CIRCUITS SHORTED TO VOLTAGE
WSS SIGNAL CIRCUITS SHORTED TO GROUND
WSS SIGNAL CIRCUITS OPEN/HIGH RESISTANCE
WSS GROUND CIRCUIT OPEN/HIGH RESISTANCE
DAMAGED TONE WHEEL
FAULTY WHEEL SPEED SENSOR
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

DIAGNOSTIC OVERVIEW

NON-eBOOSTER SYSTEM: When any faults are present against the BPP Sensor in the BSCM or PCM, the sensor and circuits should always be checked before condemning a module. While the Master Cylinder Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an ICU assembly.

eBOOSTER SYSTEM: While the BPP Sensors, Brake Pedal Simulator Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an eBooster assembly.

WHEEL SPEED SENSORS: When the vehicle is moving, the Wheel Speed Sensor signals are rationalized against each other for a stuck sensor. The controller is able to determine difference between a fault and a normal vehicle turning event (explained below).

WHEEL SPEED SENSOR COMPARISONS MONITORED	
Left Front vs Right Front	LF/RF
Left Front vs Left Rear	LF/LR
Left Front vs Right Rear	LF/RR
Right Front vs Left Rear	RF/LR
Right Front vs Right Rear	RF/RR
Left Rear vs Right Rear	LR/RR

The **enable condition threshold** is used as the comparison threshold. The threshold is calculated by taking the average of the six comparison calculations in the table when the vehicle is moving.

- **Driving Straight** - When the vehicle is moving in a straight line (steering wheel angle is near zero) the four sensor signal outputs should be relatively equal. If the LF sensor was stuck, the difference in the three calculations between the LF and other three sensors (LF/RF, LF/LR, LF/RR) will be above the enable condition threshold and the other three calculations (RF/LR, RF/RR, LR/RR) will be below the enable condition threshold, indicating a LF Wheel Speed Sensor failure.
- **Turning** - When the vehicle is turning all of the comparison checks will be different. The differences for all of the comparison checks will increase as the turning radius increases. If all comparison checks are above the calculated enable condition threshold, the vehicle is considered to be in a significant turning event and the diagnostic is temporarily disabled.
- **Vehicle Stopped** - When the vehicle is stopped each Wheel Speed Sensor signal should be 0. If three sensor outputs equal 0 and the forth is above 0 for a calibrated period threshold, the sensor is determined to be irrational.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.
2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connection issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the appropriate wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

DIAGNOSTIC TEST - NON-EBOOSTER BRAKE SYSTEM - PCM

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.

2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

BRAKE PEDAL POSITION SENSOR CIRCUIT FAULTS (P057C, P057D): TECH TIP: Typical three wire sensors must have voltage present on the 5-Volt Supply circuit to function properly. No voltage on the 5-Volt Supply circuit can cause the sensor to react one of two ways, depending on the type of sensor being used. The first is the sensor signal voltage can be stuck mid range (2.4-2.6 volts), and not change which can cause a performance fault. The second is the signal voltage can be stuck low (0 volts) since the ECU is using a pull-down signal.

1. Check the sensor harness connector for proper connection at the BPP Sensor. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the BPP Sensor harness connector and check for any pushed out, damaged, corroded or spread terminals.
2. Measure the voltage on the 5-Volt Supply circuit with the ignition on. The voltage should measure above 4.9 volts.
    1. If voltage is present, continue to step 3.
    2. If no voltage is present at the harness connector, repair the 5-Volt Supply circuit for an open or high resistance.
3. This step is designed to determine if the fault is being caused by a faulty sensor. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the BPP Sensor signal and 5-Volt Supply circuit at the BPP Sensor harness connector. A fused jumper can also be used for this step. Move the switch on the Electrical Test Lead Kit to the CLOSED position while either monitoring the voltage or fault screen on the scan tool. The voltage should read 5.0v if available, or the circuit high fault should be active. Next, connect the leads between the signal circuit and the sensor circuit at the BPP Sensor harness connector. The voltage should read 0v if available, or the circuit low fault should be active.

NOTE: **Since the BSCM uses a pull down signal, simply disconnecting the sensor harness connector should also give the same results.**

1. If the voltage or faults appear as described above, the BPP Sensor is most likely faulty.
2. If the voltage remains at 0v and only the circuit low fault is active, continue to step 4.

4. Disconnect the BSCM harness connector to isolate the circuits and check the sensor signal circuit for continuity to both chassis ground and the sensor ground circuit.

    1. If there is continuity to either, repair the signal circuit for a short to chassis ground or the sensor ground circuit.
    2. If the signal circuit is not shorted, continue to step 5.
5. Measure the resistance of the sensor signal and sensor ground circuits. Typically the circuit resistance should be less than 5.0 Ohms.
    1. If there is an open or high resistance in either circuit, repair the signal circuit for an open or high resistance.
    2. If the temp sensor signal and ground circuits test good, Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning BSCM. If no issues are found, replace the BSCM in accordance with the service information.

PCM SYSTEM PERFORMANCE FAULTS (P057B, C053D, C10F5): The signal performance faults set when one of the following signals received from the BSCM is irrational when compared to the others. The rationality checks are only done during a driver initiated braking event, not during an autonomous braking event.

- P057B - Brake Pedal Position signal is irrational.
- C053D - Master Cylinder Pressure signal is irrational.
- C10F5 - Brake Torque signal is irrational.

The Master Cylinder Pressure Sensor is internal to the Hydraulic Control Unit (HCU). The Brake Torque signal is calculated by the BSCM. The calculation is based on the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. If one of these signals is irrational, the HCU or BSCM are likely faulty.

1. If the P057B fault is present, perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
    - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
    - If the BSCM and terminals appear good, replace the eBooster assembly in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM IMPLAUSIBLE DATA FAULT (U11BF): The lost brake signal fault sets when the BSCM detects a fault against the Brake Pedal Pressure Sensor and has no rational signal to send to the PCM.

1. There should be a circuit fault set in the PCM, BSCM or both. Perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
    - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
    - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some**

vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

PCM IMPLAUSIBLE DATA FAULT (U0418): The implausible data fault sets when the BSCM detects a fault against the Master Cylinder Pressure Sensor and has no rational signal to send to the PCM.

1. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
    - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
    - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM LOSS OF COMMUNICATION FAULTS (U0121, U0129): The U0121 fault sets when the PCM does not receive the Brake Pedal Position Sensor signal message from the BSCM and the U0129 fault sets when the PCM does not receive the Master Cylinder Pressure Sensor signal message. Perform the following diagnostic checks for the Brake System Control Module:

1. Check for any Service Bulletins, Star On-line Cases, PCM or BSCM flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause a DTC.
3. Verify the vehicle modules are configured correctly. An incorrect configuration can cause a Loss of Communication fault.
4. Using the wiring information as a guide, check the fuse or fuses that supply power to BSCM. Verify the fuse(s) are not open and has a good connection with the terminals in the PDC
    1. If the fuse(s) are good, continue testing in step 5.
    2. If a fuse is open, check the supply circuit for a short to ground before replacing the fuse.
5. 
    Disconnect the BSCM harness connector and load test the Battery Supply and Ignition circuits.

    1. A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing

information and alternative methods of load testing or voltage drop testing a circuit. Refer to **CIRCUIT LOAD TESTING PROCEDURES** .

2. To verify that there is no resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. The voltage drop across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.
    - If either circuit fails the load testing, repair the resistance in the circuit. If the fuse that supplies power to the module is open or damaged
    - If both circuits pass the load test, continue testing in step 6.

6. 
Load test the BSCM Ground circuit.

1. If the ground circuit fails load testing, repair the BSCM chassis ground.
2. If the ground circuit tests good, continue testing in step 7.

7. Check the voltage on the CAN Bus (+) and CAN Bus (-) circuits at the BSCM. Typically the CAN Bus (+) voltage should be approximately 2.6v and CAN Bus (-) voltage should be approximately 2.4v.
    1. If the voltage readings do not match the values given above, check the suspect circuit for opens or shorts.

    NOTE: **A short in a Bus circuit would likely cause a Bus Performance fault or affect several modules. If only one module has Loss of Communication faults logged against it due to a wiring issue, it would likely be due to an open in a Bus circuit in the module harness connector or the wiring leading to that module.**

    2. If both voltage readings match the values given, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the BSCM. To check for an intermittent condition, connect a lab scope to both circuits at the BSCM connector and wiggle test to the wiring harnesses monitoring for a drop in either Bus circuit. If no issues are found, replace the BSCM in accordance with the service information.

The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

DIAGNOSTIC TEST-WHEEL SPEED SENSOR FAULTS

PCM RELATED WHEEL SPEED SENSOR SIGNAL FAULTS (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418)

BSCM RELATED WHEEL SPEED SENSOR FAULTS - The BSCM performs the following diagnostic checks on the Wheel Speed Sensors

- Signal circuit continuity check (C0031-1D, C0034-1D, C0036-1D, C0037-1D)

- Erratic signal check (C0031-2F, C0034-2F, C0036-2F, C0037-2F)
- Incorrect component installed check - (C0031-4A, C0034-4A, C0036-4A, C0037-4A) - front and rear sensors are not compatible on some vehicles.
- Rationality check (C0031-62, C0034-62, C0036-62, C0037-62)

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

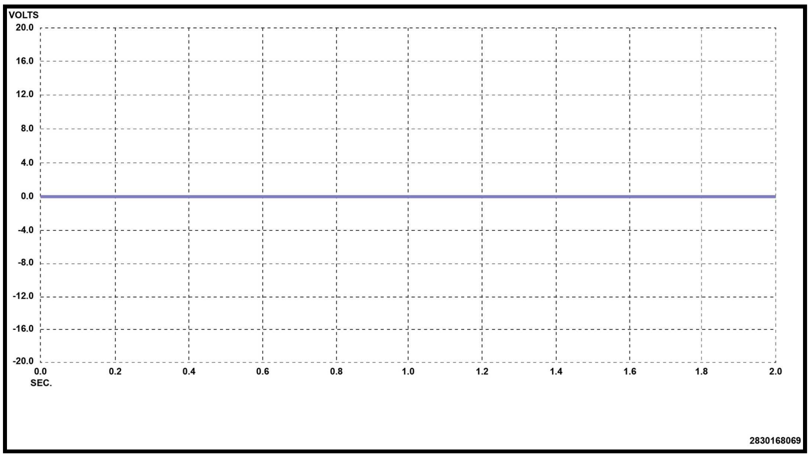
DIAGNOSING AN INCORRECT COMPONENT INSTALLED FAULT IN BSCM (C0031-4A, C0034-4A, C0036-4A, C0037-4A):

1. Some vehicles use a non-directional front WSS and directional rear WSS. The sensors are not interchangeable. Verify the correct WSS is installed on the vehicle for this fault.
    1. If the wrong part is installed, replace the WSS with the correct part number and verify repair.
    2. If the correct part is installed, replace the WSS. Clear the DTC, test drive the vehicle and confirm repair. If the DTC returns replace the Brake System Control Module in accordance with the Service Information.

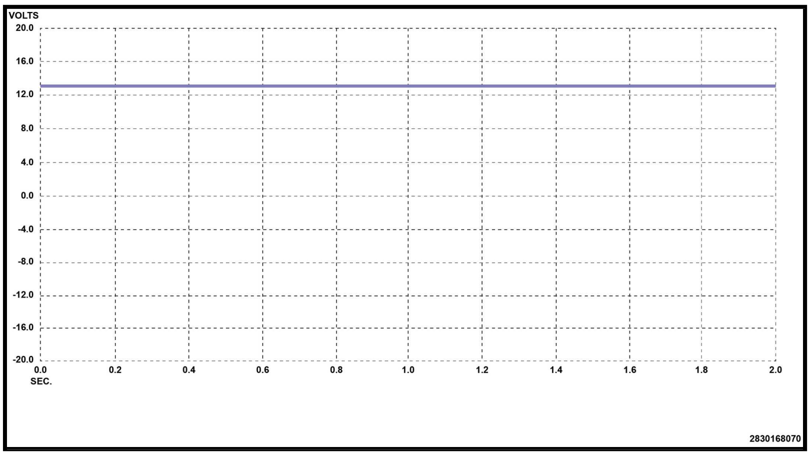
PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A LAB SCOPE - PREFERRED METHOD (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

1. Turn the ignition on. At the WSS harness connector, back probe the WSS signal circuit with the lab scope test lead. The harness connector should be plugged into the WSS. Raise the vehicle on a hoist and turn the wheel while monitoring the scope signal. There should be a consistent square wave signal cycling between 0v and some voltage. The voltage may vary depending on the vehicle. The frequency of the signal will change with the speed of the wheel but the consistency of the pattern should not. While turning the wheel watch the signal closely for the following. Inconsistency in the signal (gaps too large or small) due to a defective tone wheel/encoder or a loose, damaged sensor. A signal that is stuck high or stuck low. A signal that falls off intermittently or at lower speeds. Pick the scenario that best matches the results.
    1. **The square wave signal is consistently cycling** - the sensor signal is giving a legitimate reading. The WSS and wiring are performing properly. Test drive the vehicle while monitoring the sensors. If the signal is erratic or dropping off during the test drive, check the sensor, wheel bearing and hub for looseness or damage that may not be showing up on the hoist. If the sensor reads correctly during the test drive and the fault is active, the BSCM is likely faulty. Always check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.
    2. **The square wave signal is cycling but has erratic gaps or periodically drops off** - All of the issues listed can cause an erratic signal.
        - Check the WSS for physical damage and verify it is mounted and fastened properly.
        - If equipped with a tone wheel, inspect the tone wheel for physical damage.
        - On vehicles with encoders check the wheel bearing and hub for a worn bearing or excessive runout.
        - If no damage is found in the WSS, tone wheel, hub or wheel bearing assembly, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent circuit issue. If no issues are found, replace the Wheel Speed Sensor and verify repair.

3. **The signal has a constant 0.0 volt reading** - this indicates that the WSS Signal circuit is shorted to ground or has an open between the BSCM and WSS. Disconnect the WSS and BSCM harness connectors. Check the WSS Signal circuit for high resistance or a short to ground. If the WSS Signal circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.



4. **The signal reading has a constant voltage** - this indicates an open further downstream in the circuitry. Most likely the WSS or the Sensor Ground circuit. Continue testing in step 2.



2. To check the WSS, back probe and attach a scope lead to the Sensor Ground circuit at the WSS harness connector.
   1. **If the Sensor Ground circuit voltage is reading a constant 0.0 volts** - this would indicate an open in, or short across the WSS. The WSS is the faulty.
   2. **If the Sensor Ground circuit has a constant voltage** - this indicates an open in the Sensor Ground circuit path. Disconnect the WSS and BSCM harness connectors. Check the Sensor Ground circuit for high resistance. If the Sensor Ground circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A DVOM (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

1. Check the WSS harness connector for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the WSS harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.
2. Turn the ignition on and measure the voltage across the WSS (+) and WSS (-) circuits at the WSS harness connector. If both circuits are good there should be voltage present.

    1. If the voltage reads above 10.0 volts, the BSCM and circuits are testing good. Wiggle test the wiring while monitoring the voltage to check for an intermittent connection. If the voltage is steady above 10.0 volts, the Wheel Speed Sensor is likely faulty. Replace the Wheel Speed Sensor and verify repair.
    2. If no voltage is present, continue testing in step 3.
3. Remove the DVOM test lead from the WSS (-) circuit and connect to a good chassis ground. Measure the voltage on the WSS (+) circuit.
    1. If the voltage reads above 10.0 volts with the DVOM connected to chassis ground, the WSS (-) circuit is likely open or has high resistance between the WSS and the BSCM. If the circuit tests good (no resistance), the BSCM internal ground is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
    2. If no voltage is present on the WSS (+) circuit with the DVOM connected to chassis ground, continue testing in step 4.
4. Turn the ignition off and disconnect the BSCM harness connector. Check the WSS (+) circuit for continuity to both chassis ground and the WSS (-) circuit at the WSS harness connector.
    1. If there is continuity to either, repair the WSS (+) circuit for a short to ground or the WSS (-) circuit.
    2. If the signal circuit is not shorted, continue testing in step 5.
5. Measure the resistance of the WSS (+) circuit between the WSS harness connector and BSCM harness connector. There should be less than 3.0 Ohms of resistance.
    1. If the resistance is below 3.0 Ohms, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
    2. If the resistance is above 3.0 Ohms, repair the WSS (+) circuit for an open or high resistance.

C050D-WHEEL SPEED SIGNAL LEFT REAR RATIONALITY

For a complete BRAKE SYSTEM wiring diagram, **refer to the appropriate wiring information** .

DESCRIPTION AND OPERATION-BRAKING SYSTEMS

GENERAL NON-eBOOSTER BRAKING SYSTEM OPERATION: The Integrated Control Unit (ICU) consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The BSCM monitors the signal from the Brake Pedal Position (BPP) Sensor mounted on the Brake Pedal assembly and Master Cylinder Pressure (MCP) Sensor signal, mounted inside the HCU to detect when the Brake Pedal is applied. The BSCM also monitors the pressure sensors in each hydraulic circuit to calculate the Brake Torque signal. The calculation is based on the sum of pressure applied to the caliper in each hydraulic circuit. These signals are broadcast on the CAN bus. When the BSCM receives an autonomous brake input it controls a motor/actuator inside the Hydraulic Assembly to apply hydraulic pressure to the calipers to brake the vehicle.

GENERAL eBOOSTER BRAKING SYSTEM OPERATION: The Electronic Booster (eBooster) system consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The system does not use a conventional Master Cylinder mounted on the booster. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. To maintain normal Brake Pedal feel, when the Brake Pedal is pressed it creates hydraulic pressure in a fluid filled chamber inside the HCU. The pressure acts on a cap and spring inside the chamber allowing the pedal to get firm. This system uses a Brake Pedal Simulator Pressure Sensor in place of the MCP Sensor and two unique Brake Pedal Position (BPP) Sensors to monitor for an operator braking input. The BSCM monitors these and other inputs, and controls a motor/actuator inside the HCU to apply hydraulic pressure to the calipers during an operator braking input or autonomous braking event.

NOTE: **If the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.**

WHEEL SPEED SENSOR OPERATION: Wheel Speed Sensors (WSS) are used to monitor vehicle speed and wheel slip conditions. The Wheel Speed Sensors are hard-wired to the Brake System Control Module. The BSCM broadcasts the WSS signals on the CAN bus. The BSCM performs circuit fault diagnostics for the WSS sensors and wiring. The BSCM and PCM perform rationality checks against the outputs from the sensors. **This is described in detail in the DIAGNOSTIC OVERVIEW information below.** The WSS signals are also compared to the Steering Wheel Angle and Dynamic Sensors. Comparing these signals together can determine when the vehicle is in a turning event or if there is a fault in one of the WSS signals.

ANTI-LOCK BRAKING EVENT: During a braking event, the BSCM monitors the WSS signals to detect a wheel lock condition due to a skid event. If a wheel is determined to be locked, the BSCM cycles the Outlet Valve. Cycling the valve off/on relieves and applies the pressure to the wheel to correct the condition. The pressure will be regulated until the wheel lock condition is no longer present.

TRACTION CONTROL AND ELECTRONIC STABILITY CONTROL (ESC): If a wheel spin condition is detected during driving, and the brakes are not being applied, the BSCM will cycle the Inlet Valve in the system, applying braking to the wheel to correct the wheel slip condition. The system monitors the steering wheel angle, yaw rate and lateral acceleration (Dynamic Sensor) and Wheel Speed Sensors to determine an over/under steer condition. The BSCM will open the appropriate Inlet Valves, applying braking to counteract the condition.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE PEDAL POSITION SENSOR

NON-eBOOSTER SYSTEMS: 3-Wire Position Sensor - The Non-eBooster systems use a single Brake Pedal Position Sensor mounted on the Brake Pedal assembly. The BSCM provides the sensor with a 5-Volt reference, a pull down signal and sensor ground circuit. Using a pull down signal means that there will be 0 volts on the signal circuit when the connector is unplugged. The sensor is hard-wired to the BSCM. The BSCM converts the analog voltage signal to a digital signal and broadcasts it on the CAN bus. When the pedal is not pressed, the signal voltage is low. As the driver presses on the Brake Pedal, the voltage on the signal increases. The Minimum (Not pressed) and maximum (Pedal fully pressed) thresholds for the sensors are learned into the BSCM and PCM. **These thresholds must be re-learned using the scan tool every time a sensor, BSCM or PCM is replaced. If these thresholds are not learned, a performance fault will set.**

eBOOSTER SYSTEMS: Single Edge Nibble Transmission (SENT) Sensors - The eBooster system uses two SENT interface protocol sensors used to detect brake pedal travel. These sensors are internal to the Hydraulic Control Unit assembly. As the driver presses on the Brake Pedal, the Brake Pedal Position Sensors send an output only digital signal to the BSCM in percentage of travel. These sensors consist of three circuits, a power supply and ground circuit to function, and a digital output signal circuit. The power supply range is typically between 4.75 and 5.25 volts.

COMPONENT FUNCTIONAL DESCRIPTION - HYDRAULIC CONTROL UNIT (HCU) ASSEMBLY

The HCU Assembly internal components are slightly different depending on the brake system. The functionality of applying the brakes is also different. During an Anti-lock braking, traction control or stability control event, the functionality of the systems is relatively the same.

- **NON-eBOOSTER SYSTEMS:** The HCU on this system incorporates a Master Cylinder Pressure (MCP) Sensor, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The Brake Pedal Position Sensor is external, but hard-wired to the BSCM. The BSCM in this system is capable of operating the motor/actuator inside the HCU to apply the brakes during an autonomous braking event. The vehicle operator can directly brake the vehicle by pressing on the Brake Pedal.
- **eBOOSTER SYSTEMS:** The HCU on this system incorporates a Brake Pedal Simulator Pressure Sensor, two Brake Pedal Position (BPP) Sensors, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The BSCM in this system operates the motor/actuator to apply the brakes

during both vehicle operator input and autonomous braking events. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. However, if the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.

The Inlet Valves allow the fluid and hydraulic pressure to the calipers in each hydraulic circuit. The Outlet Valves are used to relieve the pressure in each circuit. There are two pressure sensors located in each hydraulic circuit that allow the BSCM to monitor the pressure in the system for each circuit.

COMPONENT FUNCTIONAL DESCRIPTION - WHEEL SPEED SENSORS

The Wheel Speed Sensors can be a magnetic pickup type or Hall Effect type sensor depending on the system being used. Each system uses a different type of target. The BSCM provides a signal voltage to the sensor and a ground path. The signal voltage can be 5v or 12v depending on the system.

- The system with magnetic pickup type sensors typically use a metal tone wheel that can be mounted on the hub/bearing assembly or front axle shaft. The tone wheel will have high and low spots equally spaced around the tone wheel. As the wheel is turning the high/low spots on the tone wheel pass the magnet in the sensor causing a square wave 5v or 12v signal.
- The system with Hall Effect sensors use a magnetic pole encoder that is typically incorporated in the wheel bearing assembly. With this system the air gap between the WSS and encoders is not adjustable. As the wheel is turning the magnets in the encoder pass the Hall Effect sensor causing a square wave 5v or 12v signal.

The PCM uses the Wheel Speed Sensor signals and Steering Angle Sensor signal for Engine Stop/Start enabling and oil aeration detection. The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the wheel speed signals are showing vehicle speed present, the PCM will disable ESS mode.
- If the vehicle is in a hard turning event, as determined by the wheel speed signals the oil can be dispersed to one side of the oil pan away from the pickup tube on some vehicles. This can cause oil aeration and affect the valve timing performance fault detection. During a hard turning event the valve timing performance diagnostics will be suspended until the event ends.

COMPONENT FUNCTIONAL DESCRIPTION - STEERING ANGLE SENSOR

Depending on the vehicle, the Steering Angle Sensor (SAS) can be mounted on the Steering Column, or incorporated into the Steering Column Control Module (SCCM) or Steering Gear. The SAS signal is broadcast on the CAN bus. The SAS signal is used by several modules to monitor the Steering Wheel position and rate of change for vehicle stability control, Engine Stop/Start enabling and autonomous operations.

The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the steering angle input is high (wheel turned) when the vehicle comes to a stop, and the vehicle is equipped with Electric Power Steering, the PCM will disable ESS mode. The Electric Power Steering can draw Battery voltage down quickly if the wheel is turned significantly and the engine is turned off.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE SYSTEM CONTROL MODULE (BSCM)

The BSCM is bolted to the Hydraulic Assembly. The BSCM monitors several inputs used for normal vehicle braking as well as detection and operation of anti-lock braking, traction, and electronic stability controls. The signals that are monitored are listed below. The BSCM directly monitors the signals for operating the:

- Brake Pedal Position Sensor(s)
- Master Cylinder Pressure Sensor (non-eBooster System)
- Brake Pedal Simulator Pressure Sensor (eBooster System)

- Hydraulic pressure sensors in each hydraulic circuit
- Wheel Speed Sensors
- Steering Angle Sensor
- Dynamic Sensor

These inputs are used to control the following output devices:

- Motor/actuator
- Hydraulic pump
- Inlet Check Valves
- Outlet Check Valves

TECHNICAL DATA-BRAKING SYSTEM MESSAGES

NON-eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM broadcasts the BPP Sensor signal voltage on the CAN bus. If the sensor signal is faulty, the BSCM sets a fault against the sensor and sends a Signal Not Available (SNA) message on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Master Cylinder Pressure Signal	Actual hydraulic pressure in the Master Cylinder	If the Master Cylinder Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends an SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Torque Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal is broadcast on the CAN bus.

eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM sends the average of the two BPP Sensor signal inputs on the CAN bus. If one sensor is faulted, the BSCM sets a fault against the sensor and sends the input from only the good sensor on the CAN bus. The PCM will function normally if only one sensor is faulty. If both sensors are faulty, the BSCM sets a fault against both sensors and sends a Signal Not Available (SNA) signal on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
Brake Pedal Pressure Signal	Simulated Brake Pedal applied pressure	If the Brake Pedal Simulator Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends and SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Boost Pressure Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal broadcast on the CAN bus.
BSCM Readiness Flag	Informs PCM that ESS can be performed.	The BSCM sends an ESS readiness flag (TRUE) message when the BSCM determines that ESS can be enabled. This is based on hydraulic pressure to the calipers and road grade calculation.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

Performance Faults (P057B/C053D/C10F5):

- With the ignition on.
- Battery voltage above 10.4 volts.
- No Loss of Communication or implausible/missing message faults active.

Communication Faults (U0121/U0129/U0418/U11BF):

- With the ignition on.
- Battery voltage above 10.4 volts.

Wheel Speed Sensor Signal and Distance Faults (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418):

- With the ignition on.
- Battery voltage between 9.0 and 16.0 volts.

SET CONDITION

- **C053D** - The PCM determines that the Master Cylinder Pressure Sensor signal is irrational.
- **C10F5** - The PCM determines that the Brake Torque signal is irrational.
- **P057B** - The PCM determines that the Brake Pedal Position Sensor signal is irrational.
- **U0121** - The PCM does not receive the Brake Pedal Position Sensor signal.
- **U0129** - The PCM does not receive the Master Cylinder Pressure Sensor signal.
- **U0418** - The PCM receives an SNA message indicating that the has detected a fault in the Master Cylinder Pressure Sensor signal.
- **U11BF** - The PCM receives an SNA message indicating that the has detected a fault in the Brake Pedal Position Sensor signal.
- **(C0501, C0507, C050D, C0513) Wheel Speed Signal Rationality Faults** - When at a stop, one WSS signal is showing vehicles speed output and the other three WSS signals are reading 0 OR When the difference between one WSS signal compared to the other three WSS signals is more than 11 MPH, for 30 seconds.
- **(U1409, U140A, U140B, U140C, U1412, U1417, U1418) Implausible Wheel Speed and Distance Signal Faults** - These faults will typically set when the BSCM detects a fault with one of the WSS

signals. The BSCM will send an SNA or error flag against the sensor.

The (P057B, P057C, P057D, U11BF) BPP Sensor faults can set for any of the following:

DEFAULT ACTION

- The MIL will illuminate.
- ESS System is disabled.

POSSIBLE CAUSES

POSSIBLE CAUSES
5-VOLT SUPPLY CIRCUIT OPEN OR SHORTED TO GROUND
BPP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH)
BPP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW)
BPP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
BPP SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
FAULTY BRAKE PEDAL POSITION SENSOR
FAULTY BRAKE SYSTEM MODULE (BSM)

The (C053D, C10F5, U0418) performance and implausible/lost message faults can set for any of the following:

POSSIBLE CAUSES
FAULTY HYDRAULIC ASSEMBLY (BPP AND BRAKE SIMULATOR SENSORS ARE INTERNAL)
FAULTY BRAKE SYSTEM MODULE (BSM)

The (U0121, U0129) Loss of Communication faults can set for any of the following:

POSSIBLE CAUSES
BATTERY OR IGNITION SUPPLY TO BSM OPEN OR SHORTED TO GROUND
BSM GROUND CIRCUIT OPEN/HIGH RESISTANCE
BSM CAN BUS CIRCUITS SHORTED TO VOLTAGE
BSM CAN BUS CIRCUITS SHORTED TO GROUND
BSM CAN BUS CIRCUITS OPEN/HIGH RESISTANCE
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

The Wheel Speed Sensor faults can set for any of the following:

POSSIBLE CAUSES
SNA OR ERROR MESSAGE FROM BSCM
WSS SIGNAL CIRCUITS SHORTED TO VOLTAGE
WSS SIGNAL CIRCUITS SHORTED TO GROUND
WSS SIGNAL CIRCUITS OPEN/HIGH RESISTANCE
WSS GROUND CIRCUIT OPEN/HIGH RESISTANCE
DAMAGED TONE WHEEL
FAULTY WHEEL SPEED SENSOR
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

DIAGNOSTIC OVERVIEW

NON-eBOOSTER SYSTEM: When any faults are present against the BPP Sensor in the BSCM or PCM, the sensor and circuits should always be checked before condemning a module. While the Master Cylinder Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU

and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an ICU assembly.

eBOOSTER SYSTEM: While the BPP Sensors, Brake Pedal Simulator Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an eBooster assembly.

WHEEL SPEED SENSORS: When the vehicle is moving, the Wheel Speed Sensor signals are rationalized against each other for a stuck sensor. The controller is able to determine difference between a fault and a normal vehicle turning event (explained below).

WHEEL SPEED SENSOR COMPARISONS MONITORED	
Left Front vs Right Front	LF/RF
Left Front vs Left Rear	LF/LR
Left Front vs Right Rear	LF/RR
Right Front vs Left Rear	RF/LR
Right Front vs Right Rear	RF/RR
Left Rear vs Right Rear	LR/RR

The **enable condition threshold** is used as the comparison threshold. The threshold is calculated by taking the average of the six comparison calculations in the table when the vehicle is moving.

- **Driving Straight** - When the vehicle is moving in a straight line (steering wheel angle is near zero) the four sensor signal outputs should be relatively equal. If the LF sensor was stuck, the difference in the three calculations between the LF and other three sensors (LF/RF, LF/LR, LF/RR) will be above the enable condition threshold and the other three calculations (RF/LR, RF/RR, LR/RR) will be below the enable condition threshold, indicating a LF Wheel Speed Sensor failure.
- **Turning** - When the vehicle is turning all of the comparison checks will be different. The differences for all of the comparison checks will increase as the turning radius increases. If all comparison checks are above the calculated enable condition threshold, the vehicle is considered to be in a significant turning event and the diagnostic is temporarily disabled.
- **Vehicle Stopped** - When the vehicle is stopped each Wheel Speed Sensor signal should be 0. If three sensor outputs equal 0 and the forth is above 0 for a calibrated period threshold, the sensor is determined to be irrational.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.

2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connection issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the appropriate wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

DIAGNOSTIC TEST - NON-EBOOSTER BRAKE SYSTEM - PCM

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

BRAKE PEDAL POSITION SENSOR CIRCUIT FAULTS (P057C, P057D): TECH TIP: Typical three wire sensors must have voltage present on the 5-Volt Supply circuit to function properly. No voltage on the 5-Volt Supply circuit can cause the sensor to react one of two ways, depending on the type of sensor being used. The first is the sensor signal voltage can be stuck mid range (2.4-2.6 volts), and not change which can cause a performance fault. The second is the signal voltage can be stuck low (0 volts) since the ECU is using a pull-down signal.

1. Check the sensor harness connector for proper connection at the BPP Sensor. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the BPP Sensor harness connector and check for any pushed out, damaged, corroded or spread terminals.
2. Measure the voltage on the 5-Volt Supply circuit with the ignition on. The voltage should measure above 4.9 volts.
    1. If voltage is present, continue to step 3.
    2. If no voltage is present at the harness connector, repair the 5-Volt Supply circuit for an open or high resistance.
3. This step is designed to determine if the fault is being caused by a faulty sensor. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the BPP Sensor signal and 5-Volt Supply circuit at the BPP Sensor harness connector. A fused jumper can also be used for this step. Move the switch on the Electrical Test Lead Kit to the CLOSED position while either monitoring the voltage or fault screen on the scan tool. The voltage should read 5.0v if available, or the circuit high fault should be active. Next, connect the leads between the signal circuit and the sensor circuit at the BPP Sensor harness connector. The voltage should read 0v if available, or the circuit low fault should be active.

NOTE: **Since the BSCM uses a pull down signal, simply disconnecting the sensor harness connector should also give the same results.**

    1. If the voltage or faults appear as described above, the BPP Sensor is most likely faulty.
    2. If the voltage remains at 0v and only the circuit low fault is active, continue to step 4.

4. Disconnect the BSCM harness connector to isolate the circuits and check the sensor signal circuit for continuity to both chassis ground and the sensor ground circuit.
    1. If there is continuity to either, repair the signal circuit for a short to chassis ground or the sensor ground circuit.
    2. If the signal circuit is not shorted, continue to step 5.
5. Measure the resistance of the sensor signal and sensor ground circuits. Typically the circuit resistance should be less than 5.0 Ohms.
    1. If there is an open or high resistance in either circuit, repair the signal circuit for an open or high resistance.
    2. If the temp sensor signal and ground circuits test good, Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning BSCM. If no issues are found, replace the BSCM in accordance with the service information.

PCM SYSTEM PERFORMANCE FAULTS (P057B, C053D, C10F5): The signal performance faults set when one of the following signals received from the BSCM is irrational when compared to the others. The rationality checks are only done during a driver initiated braking event, not during an autonomous braking event.

- P057B - Brake Pedal Position signal is irrational.
- C053D - Master Cylinder Pressure signal is irrational.
- C10F5 - Brake Torque signal is irrational.

The Master Cylinder Pressure Sensor is internal to the Hydraulic Control Unit (HCU). The Brake Torque signal is calculated by the BSCM. The calculation is based on the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. If one of these signals is irrational, the HCU or BSCM are likely faulty.

1. If the P057B fault is present, perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).

- If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
- If the BSCM and terminals appear good, replace the eBooster assembly in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM IMPLAUSIBLE DATA FAULT (U11BF): The lost brake signal fault sets when the BSCM detects a fault against the Brake Pedal Pressure Sensor and has no rational signal to send to the PCM.

1. There should be a circuit fault set in the PCM, BSCM or both. Perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
   - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
   - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM IMPLAUSIBLE DATA FAULT (U0418): The implausible data fault sets when the BSCM detects a fault against the Master Cylinder Pressure Sensor and has no rational signal to send to the PCM.

1. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
   - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
   - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM LOSS OF COMMUNICATION FAULTS (U0121, U0129): The U0121 fault sets when the PCM does not receive the Brake Pedal Position Sensor signal message from the BSCM and the U0129 fault sets when the PCM does not receive the Master Cylinder Pressure Sensor signal message. Perform the following diagnostic checks for the Brake System Control Module:

1. Check for any Service Bulletins, Star On-line Cases, PCM or BSCM flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause a DTC.
3. Verify the vehicle modules are configured correctly. An incorrect configuration can cause a Loss of Communication fault.

4. Using the wiring information as a guide, check the fuse or fuses that supply power to BSCM. Verify the fuse(s) are not open and has a good connection with the terminals in the PDC
    1. If the fuse(s) are good, continue testing in step 5.
    2. If a fuse is open, check the supply circuit for a short to ground before replacing the fuse.
5. 
    Disconnect the BSCM harness connector and load test the Battery Supply and Ignition circuits.

    1. A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to **CIRCUIT LOAD TESTING PROCEDURES** .
    2. To verify that there is no resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. The voltage drop across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.
        - If either circuit fails the load testing, repair the resistance in the circuit. If the fuse that supplies power to the module is open or damaged
        - If both circuits pass the load test, continue testing in step 6.
6. 
    Load test the BSCM Ground circuit.

    1. If the ground circuit fails load testing, repair the BSCM chassis ground.
    2. If the ground circuit tests good, continue testing in step 7.
7. Check the voltage on the CAN Bus (+) and CAN Bus (-) circuits at the BSCM. Typically the CAN Bus (+) voltage should be approximately 2.6v and CAN Bus (-) voltage should be approximately 2.4v.
    1. If the voltage readings do not match the values given above, check the suspect circuit for opens or shorts.

NOTE: **A short in a Bus circuit would likely cause a Bus Performance fault or affect several modules. If only one module has Loss of Communication faults logged against it due to a wiring issue, it would likely be due to an open in a Bus circuit in the module harness connector or the wiring leading to that module.**

2. If both voltage readings match the values given, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the BSCM. To check for an intermittent condition, connect a lab scope to both circuits at the BSCM connector and wiggle test to the wiring harnesses monitoring for a drop in either Bus circuit. If no issues are found, replace the BSCM in accordance with the service information.

The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

DIAGNOSTIC TEST-WHEEL SPEED SENSOR FAULTS

PCM RELATED WHEEL SPEED SENSOR SIGNAL FAULTS (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418)

BSCM RELATED WHEEL SPEED SENSOR FAULTS - The BSCM performs the following diagnostic checks on the Wheel Speed Sensors

- Signal circuit continuity check (C0031-1D, C0034-1D, C0036-1D, C0037-1D)
- Erratic signal check (C0031-2F, C0034-2F, C0036-2F, C0037-2F)
- Incorrect component installed check - (C0031-4A, C0034-4A, C0036-4A, C0037-4A) - front and rear sensors are not compatible on some vehicles.
- Rationality check (C0031-62, C0034-62, C0036-62, C0037-62)

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

DIAGNOSING AN INCORRECT COMPONENT INSTALLED FAULT IN BSCM (C0031-4A, C0034-4A, C0036-4A, C0037-4A):

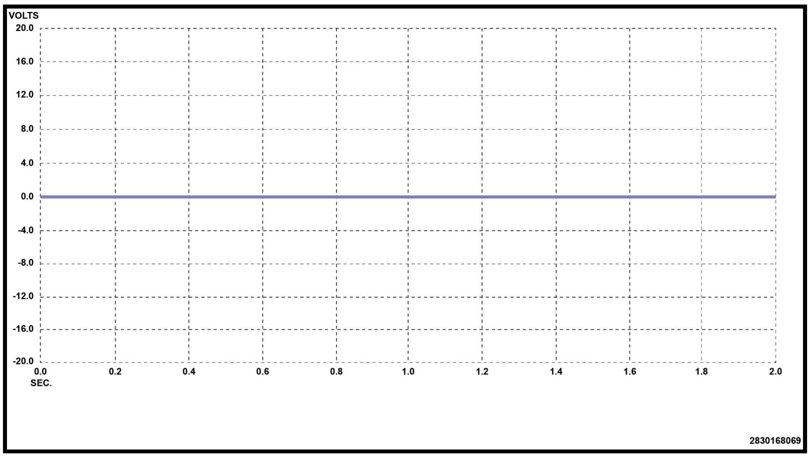
1. Some vehicles use a non-directional front WSS and directional rear WSS. The sensors are not interchangeable. Verify the correct WSS is installed on the vehicle for this fault.
    1. If the wrong part is installed, replace the WSS with the correct part number and verify repair.
    2. If the correct part is installed, replace the WSS. Clear the DTC, test drive the vehicle and confirm repair. If the DTC returns replace the Brake System Control Module in accordance with the Service Information.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A LAB SCOPE - PREFERRED METHOD (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

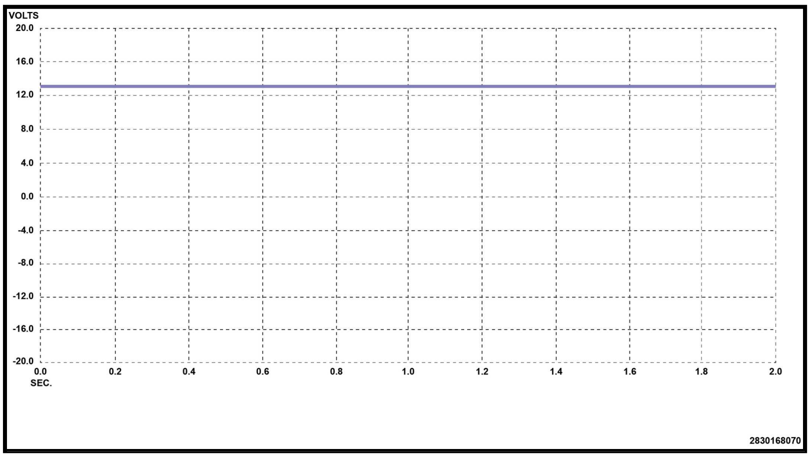
1. Turn the ignition on. At the WSS harness connector, back probe the WSS signal circuit with the lab scope test lead. The harness connector should be plugged into the WSS. Raise the vehicle on a hoist and turn the wheel while monitoring the scope signal. There should be a consistent square wave signal cycling between 0v and some voltage. The voltage may vary depending on the vehicle. The frequency of the

signal will change with the speed of the wheel but the consistency of the pattern should not. While turning the wheel watch the signal closely for the following. Inconsistency in the signal (gaps too large or small) due to a defective tone wheel/encoder or a loose, damaged sensor. A signal that is stuck high or stuck low. A signal that falls off intermittently or at lower speeds. Pick the scenario that best matches the results.

1. **The square wave signal is consistently cycling** - the sensor signal is giving a legitimate reading. The WSS and wiring are performing properly. Test drive the vehicle while monitoring the sensors. If the signal is erratic or dropping off during the test drive, check the sensor, wheel bearing and hub for looseness or damage that may not be showing up on the hoist. If the sensor reads correctly during the test drive and the fault is active, the BSCM is likely faulty. Always check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.
2. **The square wave signal is cycling but has erratic gaps or periodically drops off** - All of the issues listed can cause an erratic signal.
    - Check the WSS for physical damage and verify it is mounted and fastened properly.
    - If equipped with a tone wheel, inspect the tone wheel for physical damage.
    - On vehicles with encoders check the wheel bearing and hub for a worn bearing or excessive runout.
    - If no damage is found in the WSS, tone wheel, hub or wheel bearing assembly, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent circuit issue. If no issues are found, replace the Wheel Speed Sensor and verify repair.
3. **The signal has a constant 0.0 volt reading** - this indicates that the WSS Signal circuit is shorted to ground or has an open between the BSCM and WSS. Disconnect the WSS and BSCM harness connectors. Check the WSS Signal circuit for high resistance or a short to ground. If the WSS Signal circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.



4. **The signal reading has a constant voltage** - this indicates an open further downstream in the circuitry. Most likely the WSS or the Sensor Ground circuit. Continue testing in step 2.



2. To check the WSS, back probe and attach a scope lead to the Sensor Ground circuit at the WSS harness connector.
    1. **If the Sensor Ground circuit voltage is reading a constant 0.0 volts** - this would indicate an open in, or short across the WSS. The WSS is the faulty.
    2. **If the Sensor Ground circuit has a constant voltage** - this indicates an open in the Sensor Ground circuit path. Disconnect the WSS and BSCM harness connectors. Check the Sensor Ground circuit for high resistance. If the Sensor Ground circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A DVOM (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

1. Check the WSS harness connector for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the WSS harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.
2. Turn the ignition on and measure the voltage across the WSS (+) and WSS (-) circuits at the WSS harness connector. If both circuits are good there should be voltage present.
    1. If the voltage reads above 10.0 volts, the BSCM and circuits are testing good. Wiggle test the wiring while monitoring the voltage to check for an intermittent connection. If the voltage is steady above 10.0 volts, the Wheel Speed Sensor is likely faulty. Replace the Wheel Speed Sensor and verify repair.
    2. If no voltage is present, continue testing in step 3.
3. Remove the DVOM test lead from the WSS (-) circuit and connect to a good chassis ground. Measure the voltage on the WSS (+) circuit.
    1. If the voltage reads above 10.0 volts with the DVOM connected to chassis ground, the WSS (-) circuit is likely open or has high resistance between the WSS and the BSCM. If the circuit tests good (no resistance), the BSCM internal ground is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
    2. If no voltage is present on the WSS (+) circuit with the DVOM connected to chassis ground, continue testing in step 4.
4. Turn the ignition off and disconnect the BSCM harness connector. Check the WSS (+) circuit for continuity to both chassis ground and the WSS (-) circuit at the WSS harness connector.
    1. If there is continuity to either, repair the WSS (+) circuit for a short to ground or the WSS (-) circuit.
    2. If the signal circuit is not shorted, continue testing in step 5.
5. Measure the resistance of the WSS (+) circuit between the WSS harness connector and BSCM harness connector. There should be less than 3.0 Ohms of resistance.

1. If the resistance is below 3.0 Ohms, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
2. If the resistance is above 3.0 Ohms, repair the WSS (+) circuit for an open or high resistance.

C0513-WHEEL SPEED SIGNAL RIGHT REAR RATIONALITY

For a complete BRAKE SYSTEM wiring diagram, **refer to the appropriate wiring information** .

DESCRIPTION AND OPERATION-BRAKING SYSTEMS

GENERAL NON-eBOOSTER BRAKING SYSTEM OPERATION: The Integrated Control Unit (ICU) consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The BSCM monitors the signal from the Brake Pedal Position (BPP) Sensor mounted on the Brake Pedal assembly and Master Cylinder Pressure (MCP) Sensor signal, mounted inside the HCU to detect when the Brake Pedal is applied. The BSCM also monitors the pressure sensors in each hydraulic circuit to calculate the Brake Torque signal. The calculation is based on the sum of pressure applied to the caliper in each hydraulic circuit. These signals are broadcast on the CAN bus. When the BSCM receives an autonomous brake input it controls a motor/actuator inside the Hydraulic Assembly to apply hydraulic pressure to the calipers to brake the vehicle.

GENERAL eBOOSTER BRAKING SYSTEM OPERATION: The Electronic Booster (eBooster) system consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The system does not use a conventional Master Cylinder mounted on the booster. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. To maintain normal Brake Pedal feel, when the Brake Pedal is pressed it creates hydraulic pressure in a fluid filled chamber inside the HCU. The pressure acts on a cap and spring inside the chamber allowing the pedal to get firm. This system uses a Brake Pedal Simulator Pressure Sensor in place of the MCP Sensor and two unique Brake Pedal Position (BPP) Sensors to monitor for an operator braking input. The BSCM monitors these and other inputs, and controls a motor/actuator inside the HCU to apply hydraulic pressure to the calipers during an operator braking input or autonomous braking event.

NOTE: **If the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.**

WHEEL SPEED SENSOR OPERATION: Wheel Speed Sensors (WSS) are used to monitor vehicle speed and wheel slip conditions. The Wheel Speed Sensors are hard-wired to the Brake System Control Module. The BSCM broadcasts the WSS signals on the CAN bus. The BSCM performs circuit fault diagnostics for the WSS sensors and wiring. The BSCM and PCM perform rationality checks against the outputs from the sensors. **This is described in detail in the DIAGNOSTIC OVERVIEW information below.** The WSS signals are also compared to the Steering Wheel Angle and Dynamic Sensors. Comparing these signals together can determine when the vehicle is in a turning event or if there is a fault in one of the WSS signals.

ANTI-LOCK BRAKING EVENT: During a braking event, the BSCM monitors the WSS signals to detect a wheel lock condition due to a skid event. If a wheel is determined to be locked, the BSCM cycles the Outlet Valve. Cycling the valve off/on relieves and applies the pressure to the wheel to correct the condition. The pressure will be regulated until the wheel lock condition is no longer present.

TRACTION CONTROL AND ELECTRONIC STABILITY CONTROL (ESC): If a wheel spin condition is detected during driving, and the brakes are not being applied, the BSCM will cycle the Inlet Valve in the system, applying braking to the wheel to correct the wheel slip condition. The system monitors the steering wheel angle, yaw rate and lateral acceleration (Dynamic Sensor) and Wheel Speed Sensors to determine an over/under steer condition. The BSCM will open the appropriate Inlet Valves, applying braking to counteract the condition.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE PEDAL POSITION SENSOR

NON-eBOOSTER SYSTEMS: 3-Wire Position Sensor - The Non-eBooster systems use a single Brake Pedal Position Sensor mounted on the Brake Pedal assembly. The BSCM provides the sensor with a 5-Volt reference, a pull down signal and sensor ground circuit. Using a pull down signal means that there will be 0 volts on the signal circuit when the connector is unplugged. The sensor is hard-wired to the BSCM. The BSCM converts the analog voltage signal to a digital signal and broadcasts it on the CAN bus. When the pedal is not pressed, the signal voltage is low. As the driver presses on the Brake Pedal, the voltage on the signal increases. The Minimum (Not pressed) and maximum (Pedal fully pressed) thresholds for the sensors are learned into the BSCM and PCM. **These thresholds must be re-learned using the scan tool every time a sensor, BSCM or PCM is replaced. If these thresholds are not learned, a performance fault will set.**

eBOOSTER SYSTEMS: Single Edge Nibble Transmission (SENT) Sensors - The eBooster system uses two SENT interface protocol sensors used to detect brake pedal travel. These sensors are internal to the Hydraulic Control Unit assembly. As the driver presses on the Brake Pedal, the Brake Pedal Position Sensors send an output only digital signal to the BSCM in percentage of travel. These sensors consist of three circuits, a power supply and ground circuit to function, and a digital output signal circuit. The power supply range is typically between 4.75 and 5.25 volts.

COMPONENT FUNCTIONAL DESCRIPTION - HYDRAULIC CONTROL UNIT (HCU) ASSEMBLY

The HCU Assembly internal components are slightly different depending on the brake system. The functionality of applying the brakes is also different. During an Anti-lock braking, traction control or stability control event, the functionality of the systems is relatively the same.

- **NON-eBOOSTER SYSTEMS:** The HCU on this system incorporates a Master Cylinder Pressure (MCP) Sensor, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The Brake Pedal Position Sensor is external, but hard-wired to the BSCM. The BSCM in this system is capable of operating the motor/actuator inside the HCU to apply the brakes during an autonomous braking event. The vehicle operator can directly brake the vehicle by pressing on the Brake Pedal.

- **eBOOSTER SYSTEMS:** The HCU on this system incorporates a Brake Pedal Simulator Pressure Sensor, two Brake Pedal Position (BPP) Sensors, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The BSCM in this system operates the motor/actuator to apply the brakes during both vehicle operator input and autonomous braking events. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. However, if the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.

The Inlet Valves allow the fluid and hydraulic pressure to the calipers in each hydraulic circuit. The Outlet Valves are used to relieve the pressure in each circuit. There are two pressure sensors located in each hydraulic circuit that allow the BSCM to monitor the pressure in the system for each circuit.

COMPONENT FUNCTIONAL DESCRIPTION - WHEEL SPEED SENSORS

The Wheel Speed Sensors can be a magnetic pickup type or Hall Effect type sensor depending on the system being used. Each system uses a different type of target. The BSCM provides a signal voltage to the sensor and a ground path. The signal voltage can be 5v or 12v depending on the system.

- The system with magnetic pickup type sensors typically use a metal tone wheel that can be mounted on the hub/bearing assembly or front axle shaft. The tone wheel will have high and low spots equally spaced around the tone wheel. As the wheel is turning the high/low spots on the tone wheel pass the magnet in the sensor causing a square wave 5v or 12v signal.
- The system with Hall Effect sensors use a magnetic pole encoder that is typically incorporated in the wheel bearing assembly. With this system the air gap between the WSS and encoders is not adjustable. As the wheel is turning the magnets in the encoder pass the Hall Effect sensor causing a square wave 5v or 12v signal.

The PCM uses the Wheel Speed Sensor signals and Steering Angle Sensor signal for Engine Stop/Start enabling and oil aeration detection. The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the wheel speed signals are showing vehicle speed present, the PCM will disable ESS mode.
- If the vehicle is in a hard turning event, as determined by the wheel speed signals the oil can be dispersed to one side of the oil pan away from the pickup tube on some vehicles. This can cause oil aeration and affect the valve timing performance fault detection. During a hard turning event the valve timing performance diagnostics will be suspended until the event ends.

COMPONENT FUNCTIONAL DESCRIPTION - STEERING ANGLE SENSOR

Depending on the vehicle, the Steering Angle Sensor (SAS) can be mounted on the Steering Column, or incorporated into the Steering Column Control Module (SCCM) or Steering Gear. The SAS signal is broadcast on the CAN bus. The SAS signal is used by several modules to monitor the Steering Wheel position and rate of change for vehicle stability control, Engine Stop/Start enabling and autonomous operations.

The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the steering angle input is high (wheel turned) when the vehicle comes to a stop, and the vehicle is equipped with Electric Power Steering, the PCM will disable ESS mode. The Electric Power Steering can draw Battery voltage down quickly if the wheel is turned significantly and the engine is turned off.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE SYSTEM CONTROL MODULE (BSCM)

The BSCM is bolted to the Hydraulic Assembly. The BSCM monitors several inputs used for normal vehicle braking as well as detection and operation of anti-lock braking, traction, and electronic stability controls. The signals that are monitored are listed below. The BSCM directly monitors the signals for operating the:

- Brake Pedal Position Sensor(s)
- Master Cylinder Pressure Sensor (non-eBooster System)
- Brake Pedal Simulator Pressure Sensor (eBooster System)
- Hydraulic pressure sensors in each hydraulic circuit
- Wheel Speed Sensors
- Steering Angle Sensor
- Dynamic Sensor

These inputs are used to control the following output devices:

- Motor/actuator
- Hydraulic pump
- Inlet Check Valves
- Outlet Check Valves

TECHNICAL DATA-BRAKING SYSTEM MESSAGES

NON-eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM broadcasts the BPP Sensor signal voltage on the CAN bus. If the sensor signal is faulty, the BSCM sets a fault against the sensor and sends a Signal Not Available (SNA) message

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
		on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Master Cylinder Pressure Signal	Actual hydraulic pressure in the Master Cylinder	If the Master Cylinder Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends an SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Torque Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal is broadcast on the CAN bus.

eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM sends the average of the two BPP Sensor signal inputs on the CAN bus. If one sensor is faulted, the BSCM sets a fault against the sensor and sends the input from only the good sensor on the CAN bus. The PCM will function normally if only one sensor is faulty. If both sensors are faulty, the BSCM sets a fault against both sensors and sends a Signal Not Available (SNA) signal on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Brake Pedal Pressure Signal	Simulated Brake Pedal applied pressure	If the Brake Pedal Simulator Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends and SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Boost Pressure Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal broadcast on the CAN bus.
BSCM Readiness Flag	Informs PCM that ESS can be performed.	The BSCM sends an ESS readiness flag (TRUE) message when the BSCM determines that ESS can be enabled. This is based on hydraulic pressure to the calipers and road grade calculation.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

Performance Faults (P057B/C053D/C10F5):

- With the ignition on.
- Battery voltage above 10.4 volts.

- No Loss of Communication or implausible/missing message faults active.

Communication Faults (U0121/U0129/U0418/U11BF):

- With the ignition on.
- Battery voltage above 10.4 volts.

Wheel Speed Sensor Signal and Distance Faults (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418):

- With the ignition on.
- Battery voltage between 9.0 and 16.0 volts.

SET CONDITION

- **C053D** - The PCM determines that the Master Cylinder Pressure Sensor signal is irrational.
- **C10F5** - The PCM determines that the Brake Torque signal is irrational.
- **P057B** - The PCM determines that the Brake Pedal Position Sensor signal is irrational.
- **U0121** - The PCM does not receive the Brake Pedal Position Sensor signal.
- **U0129** - The PCM does not receive the Master Cylinder Pressure Sensor signal.
- **U0418** - The PCM receives an SNA message indicating that the has detected a fault in the Master Cylinder Pressure Sensor signal.
- **U11BF** - The PCM receives an SNA message indicating that the has detected a fault in the Brake Pedal Position Sensor signal.
- **(C0501, C0507, C050D, C0513) Wheel Speed Signal Rationality Faults** - When at a stop, one WSS signal is showing vehicles speed output and the other three WSS signals are reading 0 OR When the difference between one WSS signal compared to the other three WSS signals is more than 11 MPH, for 30 seconds.
- **(U1409, U140A, U140B, U140C, U1412, U1417, U1418) Implausible Wheel Speed and Distance Signal Faults** - These faults will typically set when the BSCM detects a fault with one of the WSS signals. The BSCM will send an SNA or error flag against the sensor.

The (P057B, P057C, P057D, U11BF) BPP Sensor faults can set for any of the following:

DEFAULT ACTION

- The MIL will illuminate.
- ESS System is disabled.

POSSIBLE CAUSES

POSSIBLE CAUSES
5-VOLT SUPPLY CIRCUIT OPEN OR SHORTED TO GROUND
BPP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH)
BPP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW)
BPP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
BPP SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
FAULTY BRAKE PEDAL POSITION SENSOR
FAULTY BRAKE SYSTEM MODULE (BSM)

The (C053D, C10F5, U0418) performance and implausible/lost message faults can set for any of the following:

POSSIBLE CAUSES
FAULTY HYDRAULIC ASSEMBLY (BPP AND BRAKE SIMULATOR SENSORS ARE INTERNAL)
FAULTY BRAKE SYSTEM MODULE (BSM)

The (U0121, U0129) Loss of Communication faults can set for any of the following:

POSSIBLE CAUSES
BATTERY OR IGNITION SUPPLY TO BSM OPEN OR SHORTED TO GROUND
BSM GROUND CIRCUIT OPEN/HIGH RESISTANCE
BSM CAN BUS CIRCUITS SHORTED TO VOLTAGE
BSM CAN BUS CIRCUITS SHORTED TO GROUND
BSM CAN BUS CIRCUITS OPEN/HIGH RESISTANCE
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

The Wheel Speed Sensor faults can set for any of the following:

POSSIBLE CAUSES
SNA OR ERROR MESSAGE FROM BSCM
WSS SIGNAL CIRCUITS SHORTED TO VOLTAGE
WSS SIGNAL CIRCUITS SHORTED TO GROUND
WSS SIGNAL CIRCUITS OPEN/HIGH RESISTANCE
WSS GROUND CIRCUIT OPEN/HIGH RESISTANCE
DAMAGED TONE WHEEL
FAULTY WHEEL SPEED SENSOR
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

DIAGNOSTIC OVERVIEW

NON-eBOOSTER SYSTEM: When any faults are present against the BPP Sensor in the BSCM or PCM, the sensor and circuits should always be checked before condemning a module. While the Master Cylinder Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an ICU assembly.

eBOOSTER SYSTEM: While the BPP Sensors, Brake Pedal Simulator Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an eBooster assembly.

WHEEL SPEED SENSORS: When the vehicle is moving, the Wheel Speed Sensor signals are rationalized against each other for a stuck sensor. The controller is able to determine difference between a fault and a normal vehicle turning event (explained below).

WHEEL SPEED SENSOR COMPARISONS MONITORED	
Left Front vs Right Front	LF/RF
Left Front vs Left Rear	LF/LR
Left Front vs Right Rear	LF/RR
Right Front vs Left Rear	RF/LR
Right Front vs Right Rear	RF/RR
Left Rear vs Right Rear	LR/RR

The **enable condition threshold** is used as the comparison threshold. The threshold is calculated by taking the average of the six comparison calculations in the table when the vehicle is moving.

- **Driving Straight** - When the vehicle is moving in a straight line (steering wheel angle is near zero) the four sensor signal outputs should be relatively equal. If the LF sensor was stuck, the difference in the three calculations between the LF and other three sensors (LF/RF, LF/LR, LF/RR) will be above the enable condition threshold and the other three calculations (RF/LR, RF/RR, LR/RR) will be below the enable condition threshold, indicating a LF Wheel Speed Sensor failure.
- **Turning** - When the vehicle is turning all of the comparison checks will be different. The differences for all of the comparison checks will increase as the turning radius increases. If all comparison checks are above the calculated enable condition threshold, the vehicle is considered to be in a significant turning event and the diagnostic is temporarily disabled.
- **Vehicle Stopped** - When the vehicle is stopped each Wheel Speed Sensor signal should be 0. If three sensor outputs equal 0 and the forth is above 0 for a calibrated period threshold, the sensor is determined to be irrational.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.
2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connection issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the appropriate wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

DIAGNOSTIC TEST - NON-EBOOSTER BRAKE SYSTEM - PCM

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.

2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

BRAKE PEDAL POSITION SENSOR CIRCUIT FAULTS (P057C, P057D): TECH TIP: Typical three wire sensors must have voltage present on the 5-Volt Supply circuit to function properly. No voltage on the 5-Volt Supply circuit can cause the sensor to react one of two ways, depending on the type of sensor being used. The first is the sensor signal voltage can be stuck mid range (2.4-2.6 volts), and not change which can cause a performance fault. The second is the signal voltage can be stuck low (0 volts) since the ECU is using a pull-down signal.

1. Check the sensor harness connector for proper connection at the BPP Sensor. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the BPP Sensor harness connector and check for any pushed out, damaged, corroded or spread terminals.
2. Measure the voltage on the 5-Volt Supply circuit with the ignition on. The voltage should measure above 4.9 volts.
    1. If voltage is present, continue to step 3.
    2. If no voltage is present at the harness connector, repair the 5-Volt Supply circuit for an open or high resistance.
3. This step is designed to determine if the fault is being caused by a faulty sensor. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the BPP Sensor signal and 5-Volt Supply circuit at the BPP Sensor harness connector. A fused jumper can also be used for this step. Move the switch on the Electrical Test Lead Kit to the CLOSED position while either monitoring the voltage or fault screen on the scan tool. The voltage should read 5.0v if available, or the circuit high fault should be active. Next, connect the leads between the signal circuit and the sensor circuit at the BPP Sensor harness connector. The voltage should read 0v if available, or the circuit low fault should be active.

NOTE: **Since the BSCM uses a pull down signal, simply disconnecting the sensor harness connector should also give the same results.**

    1. If the voltage or faults appear as described above, the BPP Sensor is most likely faulty.
    2. If the voltage remains at 0v and only the circuit low fault is active, continue to step 4.
4. Disconnect the BSCM harness connector to isolate the circuits and check the sensor signal circuit for continuity to both chassis ground and the sensor ground circuit.

    1. If there is continuity to either, repair the signal circuit for a short to chassis ground or the sensor ground circuit.
    2. If the signal circuit is not shorted, continue to step 5.
5. Measure the resistance of the sensor signal and sensor ground circuits. Typically the circuit resistance should be less than 5.0 Ohms.
    1. If there is an open or high resistance in either circuit, repair the signal circuit for an open or high resistance.
    2. If the temp sensor signal and ground circuits test good, Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning BSCM. If no issues are found, replace the BSCM in accordance with the service information.

PCM SYSTEM PERFORMANCE FAULTS (P057B, C053D, C10F5): The signal performance faults set when one of the following signals received from the BSCM is irrational when compared to the others. The rationality checks are only done during a driver initiated braking event, not during an autonomous braking event.

- P057B - Brake Pedal Position signal is irrational.
- C053D - Master Cylinder Pressure signal is irrational.
- C10F5 - Brake Torque signal is irrational.

The Master Cylinder Pressure Sensor is internal to the Hydraulic Control Unit (HCU). The Brake Torque signal is calculated by the BSCM. The calculation is based on the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. If one of these signals is irrational, the HCU or BSCM are likely faulty.

1. If the P057B fault is present, perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
    - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
    - If the BSCM and terminals appear good, replace the eBooster assembly in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM IMPLAUSIBLE DATA FAULT (U11BF): The lost brake signal fault sets when the BSCM detects a fault against the Brake Pedal Pressure Sensor and has no rational signal to send to the PCM.

1. There should be a circuit fault set in the PCM, BSCM or both. Perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
    - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
    - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some**

vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

PCM IMPLAUSIBLE DATA FAULT (U0418): The implausible data fault sets when the BSCM detects a fault against the Master Cylinder Pressure Sensor and has no rational signal to send to the PCM.

1. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
    - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
    - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM LOSS OF COMMUNICATION FAULTS (U0121, U0129): The U0121 fault sets when the PCM does not receive the Brake Pedal Position Sensor signal message from the BSCM and the U0129 fault sets when the PCM does not receive the Master Cylinder Pressure Sensor signal message. Perform the following diagnostic checks for the Brake System Control Module:

1. Check for any Service Bulletins, Star On-line Cases, PCM or BSCM flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause a DTC.
3. Verify the vehicle modules are configured correctly. An incorrect configuration can cause a Loss of Communication fault.
4. Using the wiring information as a guide, check the fuse or fuses that supply power to BSCM. Verify the fuse(s) are not open and has a good connection with the terminals in the PDC
    1. If the fuse(s) are good, continue testing in step 5.
    2. If a fuse is open, check the supply circuit for a short to ground before replacing the fuse.
5. 
    Disconnect the BSCM harness connector and load test the Battery Supply and Ignition circuits.

    1. A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing

information and alternative methods of load testing or voltage drop testing a circuit. Refer to **CIRCUIT LOAD TESTING PROCEDURES** .

2. To verify that there is no resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. The voltage drop across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.
    - If either circuit fails the load testing, repair the resistance in the circuit. If the fuse that supplies power to the module is open or damaged
    - If both circuits pass the load test, continue testing in step 6.

6. 
   Load test the BSCM Ground circuit.

    1. If the ground circuit fails load testing, repair the BSCM chassis ground.
    2. If the ground circuit tests good, continue testing in step 7.

7. Check the voltage on the CAN Bus (+) and CAN Bus (-) circuits at the BSCM. Typically the CAN Bus (+) voltage should be approximately 2.6v and CAN Bus (-) voltage should be approximately 2.4v.
    1. If the voltage readings do not match the values given above, check the suspect circuit for opens or shorts.

    NOTE: **A short in a Bus circuit would likely cause a Bus Performance fault or affect several modules. If only one module has Loss of Communication faults logged against it due to a wiring issue, it would likely be due to an open in a Bus circuit in the module harness connector or the wiring leading to that module.**

    2. If both voltage readings match the values given, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the BSCM. To check for an intermittent condition, connect a lab scope to both circuits at the BSCM connector and wiggle test to the wiring harnesses monitoring for a drop in either Bus circuit. If no issues are found, replace the BSCM in accordance with the service information.

The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

DIAGNOSTIC TEST-WHEEL SPEED SENSOR FAULTS

PCM RELATED WHEEL SPEED SENSOR SIGNAL FAULTS (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418)

BSCM RELATED WHEEL SPEED SENSOR FAULTS - The BSCM performs the following diagnostic checks on the Wheel Speed Sensors

- Signal circuit continuity check (C0031-1D, C0034-1D, C0036-1D, C0037-1D)

- Erratic signal check (C0031-2F, C0034-2F, C0036-2F, C0037-2F)
- Incorrect component installed check - (C0031-4A, C0034-4A, C0036-4A, C0037-4A) - front and rear sensors are not compatible on some vehicles.
- Rationality check (C0031-62, C0034-62, C0036-62, C0037-62)

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

DIAGNOSING AN INCORRECT COMPONENT INSTALLED FAULT IN BSCM (C0031-4A, C0034-4A, C0036-4A, C0037-4A):

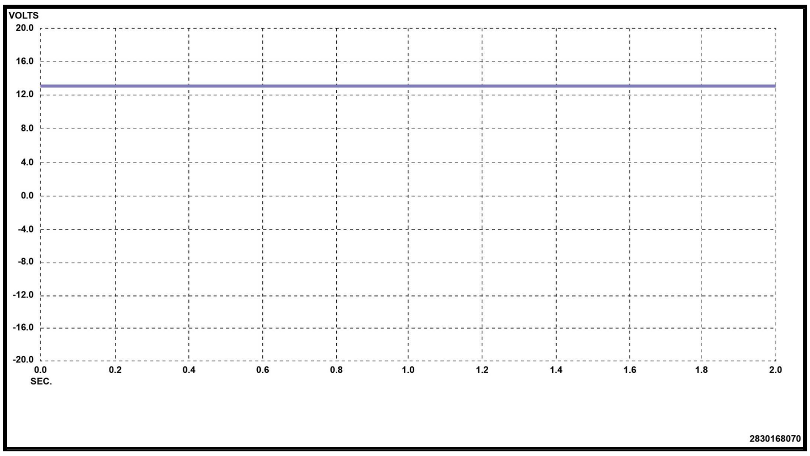
1. Some vehicles use a non-directional front WSS and directional rear WSS. The sensors are not interchangeable. Verify the correct WSS is installed on the vehicle for this fault.
    1. If the wrong part is installed, replace the WSS with the correct part number and verify repair.
    2. If the correct part is installed, replace the WSS. Clear the DTC, test drive the vehicle and confirm repair. If the DTC returns replace the Brake System Control Module in accordance with the Service Information.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A LAB SCOPE - PREFERRED METHOD (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

1. Turn the ignition on. At the WSS harness connector, back probe the WSS signal circuit with the lab scope test lead. The harness connector should be plugged into the WSS. Raise the vehicle on a hoist and turn the wheel while monitoring the scope signal. There should be a consistent square wave signal cycling between 0v and some voltage. The voltage may vary depending on the vehicle. The frequency of the signal will change with the speed of the wheel but the consistency of the pattern should not. While turning the wheel watch the signal closely for the following. Inconsistency in the signal (gaps too large or small) due to a defective tone wheel/encoder or a loose, damaged sensor. A signal that is stuck high or stuck low. A signal that falls off intermittently or at lower speeds. Pick the scenario that best matches the results.
    1. **The square wave signal is consistently cycling** - the sensor signal is giving a legitimate reading. The WSS and wiring are performing properly. Test drive the vehicle while monitoring the sensors. If the signal is erratic or dropping off during the test drive, check the sensor, wheel bearing and hub for looseness or damage that may not be showing up on the hoist. If the sensor reads correctly during the test drive and the fault is active, the BSCM is likely faulty. Always check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.
    2. **The square wave signal is cycling but has erratic gaps or periodically drops off** - All of the issues listed can cause an erratic signal.
        - Check the WSS for physical damage and verify it is mounted and fastened properly.
        - If equipped with a tone wheel, inspect the tone wheel for physical damage.
        - On vehicles with encoders check the wheel bearing and hub for a worn bearing or excessive runout.
        - If no damage is found in the WSS, tone wheel, hub or wheel bearing assembly, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent circuit issue. If no issues are found, replace the Wheel Speed Sensor and verify repair.

   3. **The signal has a constant 0.0 volt reading** - this indicates that the WSS Signal circuit is shorted to ground or has an open between the BSCM and WSS. Disconnect the WSS and BSCM harness connectors. Check the WSS Signal circuit for high resistance or a short to ground. If the WSS Signal circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.

   4. **The signal reading has a constant voltage** - this indicates an open further downstream in the circuitry. Most likely the WSS or the Sensor Ground circuit. Continue testing in step 2.



2. To check the WSS, back probe and attach a scope lead to the Sensor Ground circuit at the WSS harness connector.
   1. **If the Sensor Ground circuit voltage is reading a constant 0.0 volts** - this would indicate an open in, or short across the WSS. The WSS is the faulty.
   2. **If the Sensor Ground circuit has a constant voltage** - this indicates an open in the Sensor Ground circuit path. Disconnect the WSS and BSCM harness connectors. Check the Sensor Ground circuit for high resistance. If the Sensor Ground circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A DVOM (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

1. Check the WSS harness connector for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the WSS harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.
2. Turn the ignition on and measure the voltage across the WSS (+) and WSS (-) circuits at the WSS harness connector. If both circuits are good there should be voltage present.

    1. If the voltage reads above 10.0 volts, the BSCM and circuits are testing good. Wiggle test the wiring while monitoring the voltage to check for an intermittent connection. If the voltage is steady above 10.0 volts, the Wheel Speed Sensor is likely faulty. Replace the Wheel Speed Sensor and verify repair.
    2. If no voltage is present, continue testing in step 3.
3. Remove the DVOM test lead from the WSS (-) circuit and connect to a good chassis ground. Measure the voltage on the WSS (+) circuit.
    1. If the voltage reads above 10.0 volts with the DVOM connected to chassis ground, the WSS (-) circuit is likely open or has high resistance between the WSS and the BSCM. If the circuit tests good (no resistance), the BSCM internal ground is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
    2. If no voltage is present on the WSS (+) circuit with the DVOM connected to chassis ground, continue testing in step 4.
4. Turn the ignition off and disconnect the BSCM harness connector. Check the WSS (+) circuit for continuity to both chassis ground and the WSS (-) circuit at the WSS harness connector.
    1. If there is continuity to either, repair the WSS (+) circuit for a short to ground or the WSS (-) circuit.
    2. If the signal circuit is not shorted, continue testing in step 5.
5. Measure the resistance of the WSS (+) circuit between the WSS harness connector and BSCM harness connector. There should be less than 3.0 Ohms of resistance.
    1. If the resistance is below 3.0 Ohms, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
    2. If the resistance is above 3.0 Ohms, repair the WSS (+) circuit for an open or high resistance.

C053D-BRAKE PRESSURE SENSOR 1 PERFORMANCE

For a complete BRAKE SYSTEM wiring diagram, **refer to the appropriate wiring information** .

DESCRIPTION AND OPERATION-BRAKING SYSTEMS

GENERAL NON-eBOOSTER BRAKING SYSTEM OPERATION: The Integrated Control Unit (ICU) consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The BSCM monitors the signal from the Brake Pedal Position (BPP) Sensor mounted on the Brake Pedal assembly and Master Cylinder Pressure (MCP) Sensor signal, mounted inside the HCU to detect when the Brake Pedal is applied. The BSCM also monitors the pressure sensors in each hydraulic circuit to calculate the Brake Torque signal. The calculation is based on the sum of pressure applied to the caliper in each hydraulic circuit. These signals are broadcast on the CAN bus. When the BSCM receives an autonomous brake input it controls a motor/actuator inside the Hydraulic Assembly to apply hydraulic pressure to the calipers to brake the vehicle.

GENERAL eBOOSTER BRAKING SYSTEM OPERATION: The Electronic Booster (eBooster) system consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The system does not use a conventional Master Cylinder mounted on the booster. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. To maintain normal Brake Pedal feel, when the Brake Pedal is pressed it creates hydraulic pressure in a fluid filled chamber inside the HCU. The pressure acts on a cap and spring inside the chamber allowing the pedal to get firm. This system uses a Brake Pedal Simulator Pressure Sensor in place of the MCP Sensor and two unique Brake Pedal Position (BPP) Sensors to monitor for an operator braking input. The BSCM monitors these and other inputs, and controls a motor/actuator inside the HCU to apply hydraulic pressure to the calipers during an operator braking input or autonomous braking event.

NOTE: **If the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.**

WHEEL SPEED SENSOR OPERATION: Wheel Speed Sensors (WSS) are used to monitor vehicle speed and wheel slip conditions. The Wheel Speed Sensors are hard-wired to the Brake System Control Module. The BSCM broadcasts the WSS signals on the CAN bus. The BSCM performs circuit fault diagnostics for the WSS sensors and wiring. The BSCM and PCM perform rationality checks against the outputs from the sensors. **This is described in detail in the DIAGNOSTIC OVERVIEW information below.** The WSS signals are also compared to the Steering Wheel Angle and Dynamic Sensors. Comparing these signals together can determine when the vehicle is in a turning event or if there is a fault in one of the WSS signals.

ANTI-LOCK BRAKING EVENT: During a braking event, the BSCM monitors the WSS signals to detect a wheel lock condition due to a skid event. If a wheel is determined to be locked, the BSCM cycles the Outlet Valve. Cycling the valve off/on relieves and applies the pressure to the wheel to correct the condition. The pressure will be regulated until the wheel lock condition is no longer present.

TRACTION CONTROL AND ELECTRONIC STABILITY CONTROL (ESC): If a wheel spin condition is detected during driving, and the brakes are not being applied, the BSCM will cycle the Inlet Valve in the system, applying braking to the wheel to correct the wheel slip condition. The system monitors the steering wheel angle, yaw rate and lateral acceleration (Dynamic Sensor) and Wheel Speed Sensors to determine an over/under steer condition. The BSCM will open the appropriate Inlet Valves, applying braking to counteract the condition.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE PEDAL POSITION SENSOR

NON-eBOOSTER SYSTEMS: 3-Wire Position Sensor - The Non-eBooster systems use a single Brake Pedal Position Sensor mounted on the Brake Pedal assembly. The BSCM provides the sensor with a 5-Volt reference, a pull down signal and sensor ground circuit. Using a pull down signal means that there will be 0 volts on the signal circuit when the connector is unplugged. The sensor is hard-wired to the BSCM. The BSCM converts the analog voltage signal to a digital signal and broadcasts it on the CAN bus. When the pedal is not pressed, the signal voltage is low. As the driver presses on the Brake Pedal, the voltage on the signal increases. The Minimum (Not pressed) and maximum (Pedal fully pressed) thresholds for the sensors are learned into the BSCM and PCM. **These thresholds must be re-learned using the scan tool every time a sensor, BSCM or PCM is replaced. If these thresholds are not learned, a performance fault will set.**

eBOOSTER SYSTEMS: Single Edge Nibble Transmission (SENT) Sensors - The eBooster system uses two SENT interface protocol sensors used to detect brake pedal travel. These sensors are internal to the Hydraulic Control Unit assembly. As the driver presses on the Brake Pedal, the Brake Pedal Position Sensors send an output only digital signal to the BSCM in percentage of travel. These sensors consist of three circuits, a power supply and ground circuit to function, and a digital output signal circuit. The power supply range is typically between 4.75 and 5.25 volts.

COMPONENT FUNCTIONAL DESCRIPTION - HYDRAULIC CONTROL UNIT (HCU) ASSEMBLY

The HCU Assembly internal components are slightly different depending on the brake system. The functionality of applying the brakes is also different. During an Anti-lock braking, traction control or stability control event, the functionality of the systems is relatively the same.

- **NON-eBOOSTER SYSTEMS:** The HCU on this system incorporates a Master Cylinder Pressure (MCP) Sensor, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The Brake Pedal Position Sensor is external, but hard-wired to the BSCM. The BSCM in this system is capable of operating the motor/actuator inside the HCU to apply the brakes during an autonomous braking event. The vehicle operator can directly brake the vehicle by pressing on the Brake Pedal.
- **eBOOSTER SYSTEMS:** The HCU on this system incorporates a Brake Pedal Simulator Pressure Sensor, two Brake Pedal Position (BPP) Sensors, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The BSCM in this system operates the motor/actuator to apply the brakes

during both vehicle operator input and autonomous braking events. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. However, if the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.

The Inlet Valves allow the fluid and hydraulic pressure to the calipers in each hydraulic circuit. The Outlet Valves are used to relieve the pressure in each circuit. There are two pressure sensors located in each hydraulic circuit that allow the BSCM to monitor the pressure in the system for each circuit.

COMPONENT FUNCTIONAL DESCRIPTION - WHEEL SPEED SENSORS

The Wheel Speed Sensors can be a magnetic pickup type or Hall Effect type sensor depending on the system being used. Each system uses a different type of target. The BSCM provides a signal voltage to the sensor and a ground path. The signal voltage can be 5v or 12v depending on the system.

- The system with magnetic pickup type sensors typically use a metal tone wheel that can be mounted on the hub/bearing assembly or front axle shaft. The tone wheel will have high and low spots equally spaced around the tone wheel. As the wheel is turning the high/low spots on the tone wheel pass the magnet in the sensor causing a square wave 5v or 12v signal.
- The system with Hall Effect sensors use a magnetic pole encoder that is typically incorporated in the wheel bearing assembly. With this system the air gap between the WSS and encoders is not adjustable. As the wheel is turning the magnets in the encoder pass the Hall Effect sensor causing a square wave 5v or 12v signal.

The PCM uses the Wheel Speed Sensor signals and Steering Angle Sensor signal for Engine Stop/Start enabling and oil aeration detection. The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the wheel speed signals are showing vehicle speed present, the PCM will disable ESS mode.
- If the vehicle is in a hard turning event, as determined by the wheel speed signals the oil can be dispersed to one side of the oil pan away from the pickup tube on some vehicles. This can cause oil aeration and affect the valve timing performance fault detection. During a hard turning event the valve timing performance diagnostics will be suspended until the event ends.

COMPONENT FUNCTIONAL DESCRIPTION - STEERING ANGLE SENSOR

Depending on the vehicle, the Steering Angle Sensor (SAS) can be mounted on the Steering Column, or incorporated into the Steering Column Control Module (SCCM) or Steering Gear. The SAS signal is broadcast on the CAN bus. The SAS signal is used by several modules to monitor the Steering Wheel position and rate of change for vehicle stability control, Engine Stop/Start enabling and autonomous operations.

The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the steering angle input is high (wheel turned) when the vehicle comes to a stop, and the vehicle is equipped with Electric Power Steering, the PCM will disable ESS mode. The Electric Power Steering can draw Battery voltage down quickly if the wheel is turned significantly and the engine is turned off.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE SYSTEM CONTROL MODULE (BSCM)

The BSCM is bolted to the Hydraulic Assembly. The BSCM monitors several inputs used for normal vehicle braking as well as detection and operation of anti-lock braking, traction, and electronic stability controls. The signals that are monitored are listed below. The BSCM directly monitors the signals for operating the:

- Brake Pedal Position Sensor(s)
- Master Cylinder Pressure Sensor (non-eBooster System)
- Brake Pedal Simulator Pressure Sensor (eBooster System)

- Hydraulic pressure sensors in each hydraulic circuit
- Wheel Speed Sensors
- Steering Angle Sensor
- Dynamic Sensor

These inputs are used to control the following output devices:

- Motor/actuator
- Hydraulic pump
- Inlet Check Valves
- Outlet Check Valves

TECHNICAL DATA-BRAKING SYSTEM MESSAGES

NON-eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM broadcasts the BPP Sensor signal voltage on the CAN bus. If the sensor signal is faulty, the BSCM sets a fault against the sensor and sends a Signal Not Available (SNA) message on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Master Cylinder Pressure Signal	Actual hydraulic pressure in the Master Cylinder	If the Master Cylinder Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends an SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Torque Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal is broadcast on the CAN bus.

eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM sends the average of the two BPP Sensor signal inputs on the CAN bus. If one sensor is faulted, the BSCM sets a fault against the sensor and sends the input from only the good sensor on the CAN bus. The PCM will function normally if only one sensor is faulty. If both sensors are faulty, the BSCM sets a fault against both sensors and sends a Signal Not Available (SNA) signal on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
Brake Pedal Pressure Signal	Simulated Brake Pedal applied pressure	If the Brake Pedal Simulator Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends and SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Boost Pressure Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal broadcast on the CAN bus.
BSCM Readiness Flag	Informs PCM that ESS can be performed.	The BSCM sends an ESS readiness flag (TRUE) message when the BSCM determines that ESS can be enabled. This is based on hydraulic pressure to the calipers and road grade calculation.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

Performance Faults (P057B/C053D/C10F5):

- With the ignition on.
- Battery voltage above 10.4 volts.
- No Loss of Communication or implausible/missing message faults active.

Communication Faults (U0121/U0129/U0418/U11BF):

- With the ignition on.
- Battery voltage above 10.4 volts.

Wheel Speed Sensor Signal and Distance Faults (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418):

- With the ignition on.
- Battery voltage between 9.0 and 16.0 volts.

SET CONDITION

- **C053D** - The PCM determines that the Master Cylinder Pressure Sensor signal is irrational.
- **C10F5** - The PCM determines that the Brake Torque signal is irrational.
- **P057B** - The PCM determines that the Brake Pedal Position Sensor signal is irrational.
- **U0121** - The PCM does not receive the Brake Pedal Position Sensor signal.
- **U0129** - The PCM does not receive the Master Cylinder Pressure Sensor signal.
- **U0418** - The PCM receives an SNA message indicating that the has detected a fault in the Master Cylinder Pressure Sensor signal.
- **U11BF** - The PCM receives an SNA message indicating that the has detected a fault in the Brake Pedal Position Sensor signal.
- **(C0501, C0507, C050D, C0513) Wheel Speed Signal Rationality Faults** - When at a stop, one WSS signal is showing vehicles speed output and the other three WSS signals are reading 0 OR When the difference between one WSS signal compared to the other three WSS signals is more than 11 MPH, for 30 seconds.
- **(U1409, U140A, U140B, U140C, U1412, U1417, U1418) Implausible Wheel Speed and Distance Signal Faults** - These faults will typically set when the BSCM detects a fault with one of the WSS

signals. The BSCM will send an SNA or error flag against the sensor.

The (P057B, P057C, P057D, U11BF) BPP Sensor faults can set for any of the following:

DEFAULT ACTION

- The MIL will illuminate.
- ESS System is disabled.

POSSIBLE CAUSES

POSSIBLE CAUSES
5-VOLT SUPPLY CIRCUIT OPEN OR SHORTED TO GROUND
BPP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH)
BPP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW)
BPP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
BPP SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
FAULTY BRAKE PEDAL POSITION SENSOR
FAULTY BRAKE SYSTEM MODULE (BSM)

The (C053D, C10F5, U0418) performance and implausible/lost message faults can set for any of the following:

POSSIBLE CAUSES
FAULTY HYDRAULIC ASSEMBLY (BPP AND BRAKE SIMULATOR SENSORS ARE INTERNAL)
FAULTY BRAKE SYSTEM MODULE (BSM)

The (U0121, U0129) Loss of Communication faults can set for any of the following:

POSSIBLE CAUSES
BATTERY OR IGNITION SUPPLY TO BSM OPEN OR SHORTED TO GROUND
BSM GROUND CIRCUIT OPEN/HIGH RESISTANCE
BSM CAN BUS CIRCUITS SHORTED TO VOLTAGE
BSM CAN BUS CIRCUITS SHORTED TO GROUND
BSM CAN BUS CIRCUITS OPEN/HIGH RESISTANCE
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

The Wheel Speed Sensor faults can set for any of the following:

POSSIBLE CAUSES
SNA OR ERROR MESSAGE FROM BSCM
WSS SIGNAL CIRCUITS SHORTED TO VOLTAGE
WSS SIGNAL CIRCUITS SHORTED TO GROUND
WSS SIGNAL CIRCUITS OPEN/HIGH RESISTANCE
WSS GROUND CIRCUIT OPEN/HIGH RESISTANCE
DAMAGED TONE WHEEL
FAULTY WHEEL SPEED SENSOR
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

DIAGNOSTIC OVERVIEW

NON-eBOOSTER SYSTEM: When any faults are present against the BPP Sensor in the BSCM or PCM, the sensor and circuits should always be checked before condemning a module. While the Master Cylinder Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU

and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an ICU assembly.

eBOOSTER SYSTEM: While the BPP Sensors, Brake Pedal Simulator Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an eBooster assembly.

WHEEL SPEED SENSORS: When the vehicle is moving, the Wheel Speed Sensor signals are rationalized against each other for a stuck sensor. The controller is able to determine difference between a fault and a normal vehicle turning event (explained below).

WHEEL SPEED SENSOR COMPARISONS MONITORED	
Left Front vs Right Front	LF/RF
Left Front vs Left Rear	LF/LR
Left Front vs Right Rear	LF/RR
Right Front vs Left Rear	RF/LR
Right Front vs Right Rear	RF/RR
Left Rear vs Right Rear	LR/RR

The **enable condition threshold** is used as the comparison threshold. The threshold is calculated by taking the average of the six comparison calculations in the table when the vehicle is moving.

- **Driving Straight** - When the vehicle is moving in a straight line (steering wheel angle is near zero) the four sensor signal outputs should be relatively equal. If the LF sensor was stuck, the difference in the three calculations between the LF and other three sensors (LF/RF, LF/LR, LF/RR) will be above the enable condition threshold and the other three calculations (RF/LR, RF/RR, LR/RR) will be below the enable condition threshold, indicating a LF Wheel Speed Sensor failure.
- **Turning** - When the vehicle is turning all of the comparison checks will be different. The differences for all of the comparison checks will increase as the turning radius increases. If all comparison checks are above the calculated enable condition threshold, the vehicle is considered to be in a significant turning event and the diagnostic is temporarily disabled.
- **Vehicle Stopped** - When the vehicle is stopped each Wheel Speed Sensor signal should be 0. If three sensor outputs equal 0 and the forth is above 0 for a calibrated period threshold, the sensor is determined to be irrational.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.

2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connection issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the appropriate wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

DIAGNOSTIC TEST - NON-EBOOSTER BRAKE SYSTEM - PCM

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

BRAKE PEDAL POSITION SENSOR CIRCUIT FAULTS (P057C, P057D): TECH TIP: Typical three wire sensors must have voltage present on the 5-Volt Supply circuit to function properly. No voltage on the 5-Volt Supply circuit can cause the sensor to react one of two ways, depending on the type of sensor being used. The first is the sensor signal voltage can be stuck mid range (2.4-2.6 volts), and not change which can cause a performance fault. The second is the signal voltage can be stuck low (0 volts) since the ECU is using a pull-down signal.

1. Check the sensor harness connector for proper connection at the BPP Sensor. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the BPP Sensor harness connector and check for any pushed out, damaged, corroded or spread terminals.
2. Measure the voltage on the 5-Volt Supply circuit with the ignition on. The voltage should measure above 4.9 volts.
    1. If voltage is present, continue to step 3.
    2. If no voltage is present at the harness connector, repair the 5-Volt Supply circuit for an open or high resistance.
3. This step is designed to determine if the fault is being caused by a faulty sensor. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the BPP Sensor signal and 5-Volt Supply circuit at the BPP Sensor harness connector. A fused jumper can also be used for this step. Move the switch on the Electrical Test Lead Kit to the CLOSED position while either monitoring the voltage or fault screen on the scan tool. The voltage should read 5.0v if available, or the circuit high fault should be active. Next, connect the leads between the signal circuit and the sensor circuit at the BPP Sensor harness connector. The voltage should read 0v if available, or the circuit low fault should be active.

NOTE: **Since the BSCM uses a pull down signal, simply disconnecting the sensor harness connector should also give the same results.**

   1. If the voltage or faults appear as described above, the BPP Sensor is most likely faulty.
   2. If the voltage remains at 0v and only the circuit low fault is active, continue to step 4.
4. Disconnect the BSCM harness connector to isolate the circuits and check the sensor signal circuit for continuity to both chassis ground and the sensor ground circuit.
   1. If there is continuity to either, repair the signal circuit for a short to chassis ground or the sensor ground circuit.
   2. If the signal circuit is not shorted, continue to step 5.
5. Measure the resistance of the sensor signal and sensor ground circuits. Typically the circuit resistance should be less than 5.0 Ohms.
   1. If there is an open or high resistance in either circuit, repair the signal circuit for an open or high resistance.
   2. If the temp sensor signal and ground circuits test good, Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning BSCM. If no issues are found, replace the BSCM in accordance with the service information.

PCM SYSTEM PERFORMANCE FAULTS (P057B, C053D, C10F5): The signal performance faults set when one of the following signals received from the BSCM is irrational when compared to the others. The rationality checks are only done during a driver initiated braking event, not during an autonomous braking event.

- P057B - Brake Pedal Position signal is irrational.
- C053D - Master Cylinder Pressure signal is irrational.
- C10F5 - Brake Torque signal is irrational.

The Master Cylinder Pressure Sensor is internal to the Hydraulic Control Unit (HCU). The Brake Torque signal is calculated by the BSCM. The calculation is based on the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. If one of these signals is irrational, the HCU or BSCM are likely faulty.

1. If the P057B fault is present, perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).

- If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
- If the BSCM and terminals appear good, replace the eBooster assembly in accordance with the Service Information.

NOTE: The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

PCM IMPLAUSIBLE DATA FAULT (U11BF): The lost brake signal fault sets when the BSCM detects a fault against the Brake Pedal Pressure Sensor and has no rational signal to send to the PCM.

1. There should be a circuit fault set in the PCM, BSCM or both. Perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
   - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
   - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

PCM IMPLAUSIBLE DATA FAULT (U0418): The implausible data fault sets when the BSCM detects a fault against the Master Cylinder Pressure Sensor and has no rational signal to send to the PCM.

1. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
   - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
   - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

PCM LOSS OF COMMUNICATION FAULTS (U0121, U0129): The U0121 fault sets when the PCM does not receive the Brake Pedal Position Sensor signal message from the BSCM and the U0129 fault sets when the PCM does not receive the Master Cylinder Pressure Sensor signal message. Perform the following diagnostic checks for the Brake System Control Module:

1. Check for any Service Bulletins, Star On-line Cases, PCM or BSCM flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause a DTC.
3. Verify the vehicle modules are configured correctly. An incorrect configuration can cause a Loss of Communication fault.

4. Using the wiring information as a guide, check the fuse or fuses that supply power to BSCM. Verify the fuse(s) are not open and has a good connection with the terminals in the PDC
    1. If the fuse(s) are good, continue testing in step 5.
    2. If a fuse is open, check the supply circuit for a short to ground before replacing the fuse.
5. 
    Disconnect the BSCM harness connector and load test the Battery Supply and Ignition circuits.

    1. A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to **CIRCUIT LOAD TESTING PROCEDURES** .
    2. To verify that there is no resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. The voltage drop across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.
        - If either circuit fails the load testing, repair the resistance in the circuit. If the fuse that supplies power to the module is open or damaged
        - If both circuits pass the load test, continue testing in step 6.
6. 
    Load test the BSCM Ground circuit.

    1. If the ground circuit fails load testing, repair the BSCM chassis ground.
    2. If the ground circuit tests good, continue testing in step 7.
7. Check the voltage on the CAN Bus (+) and CAN Bus (-) circuits at the BSCM. Typically the CAN Bus (+) voltage should be approximately 2.6v and CAN Bus (-) voltage should be approximately 2.4v.
    1. If the voltage readings do not match the values given above, check the suspect circuit for opens or shorts.

NOTE: **A short in a Bus circuit would likely cause a Bus Performance fault or affect several modules. If only one module has Loss of Communication faults logged against it due to a wiring issue, it would likely be due to an open in a Bus circuit in the module harness connector or the wiring leading to that module.**

2. If both voltage readings match the values given, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the BSCM. To check for an intermittent condition, connect a lab scope to both circuits at the BSCM connector and wiggle test to the wiring harnesses monitoring for a drop in either Bus circuit. If no issues are found, replace the BSCM in accordance with the service information.

The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

DIAGNOSTIC TEST-WHEEL SPEED SENSOR FAULTS

PCM RELATED WHEEL SPEED SENSOR SIGNAL FAULTS (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418)

BSCM RELATED WHEEL SPEED SENSOR FAULTS - The BSCM performs the following diagnostic checks on the Wheel Speed Sensors

- Signal circuit continuity check (C0031-1D, C0034-1D, C0036-1D, C0037-1D)
- Erratic signal check (C0031-2F, C0034-2F, C0036-2F, C0037-2F)
- Incorrect component installed check - (C0031-4A, C0034-4A, C0036-4A, C0037-4A) - front and rear sensors are not compatible on some vehicles.
- Rationality check (C0031-62, C0034-62, C0036-62, C0037-62)

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

DIAGNOSING AN INCORRECT COMPONENT INSTALLED FAULT IN BSCM (C0031-4A, C0034-4A, C0036-4A, C0037-4A):

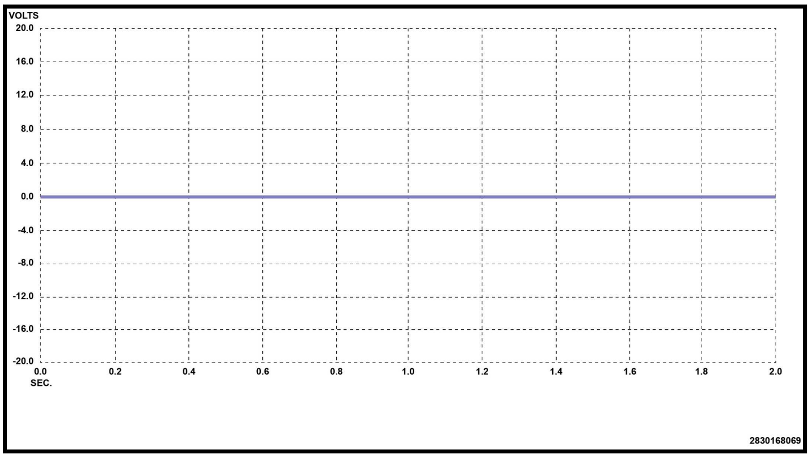
1. Some vehicles use a non-directional front WSS and directional rear WSS. The sensors are not interchangeable. Verify the correct WSS is installed on the vehicle for this fault.
   1. If the wrong part is installed, replace the WSS with the correct part number and verify repair.
   2. If the correct part is installed, replace the WSS. Clear the DTC, test drive the vehicle and confirm repair. If the DTC returns replace the Brake System Control Module in accordance with the Service Information.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A LAB SCOPE - PREFERRED METHOD (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

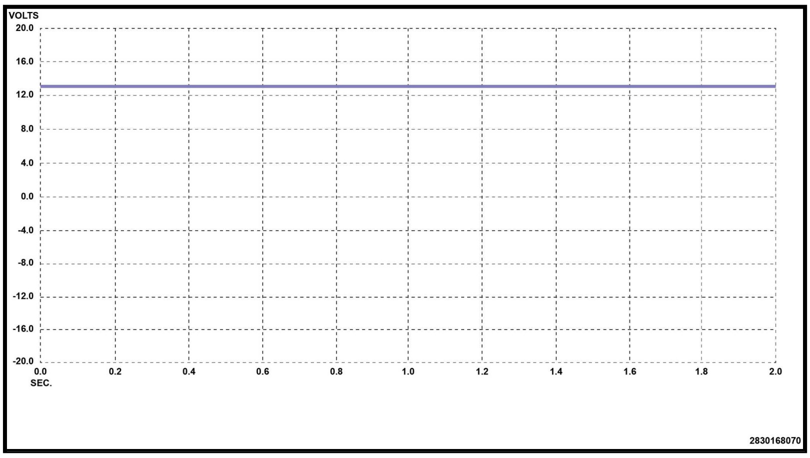
1. Turn the ignition on. At the WSS harness connector, back probe the WSS signal circuit with the lab scope test lead. The harness connector should be plugged into the WSS. Raise the vehicle on a hoist and turn the wheel while monitoring the scope signal. There should be a consistent square wave signal cycling between 0v and some voltage. The voltage may vary depending on the vehicle. The frequency of the

signal will change with the speed of the wheel but the consistency of the pattern should not. While turning the wheel watch the signal closely for the following. Inconsistency in the signal (gaps too large or small) due to a defective tone wheel/encoder or a loose, damaged sensor. A signal that is stuck high or stuck low. A signal that falls off intermittently or at lower speeds. Pick the scenario that best matches the results.

1. **The square wave signal is consistently cycling** - the sensor signal is giving a legitimate reading. The WSS and wiring are performing properly. Test drive the vehicle while monitoring the sensors. If the signal is erratic or dropping off during the test drive, check the sensor, wheel bearing and hub for looseness or damage that may not be showing up on the hoist. If the sensor reads correctly during the test drive and the fault is active, the BSCM is likely faulty. Always check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.
2. **The square wave signal is cycling but has erratic gaps or periodically drops off** - All of the issues listed can cause an erratic signal.
    - Check the WSS for physical damage and verify it is mounted and fastened properly.
    - If equipped with a tone wheel, inspect the tone wheel for physical damage.
    - On vehicles with encoders check the wheel bearing and hub for a worn bearing or excessive runout.
    - If no damage is found in the WSS, tone wheel, hub or wheel bearing assembly, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent circuit issue. If no issues are found, replace the Wheel Speed Sensor and verify repair.
3. **The signal has a constant 0.0 volt reading** - this indicates that the WSS Signal circuit is shorted to ground or has an open between the BSCM and WSS. Disconnect the WSS and BSCM harness connectors. Check the WSS Signal circuit for high resistance or a short to ground. If the WSS Signal circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.



4. **The signal reading has a constant voltage** - this indicates an open further downstream in the circuitry. Most likely the WSS or the Sensor Ground circuit. Continue testing in step 2.



2. To check the WSS, back probe and attach a scope lead to the Sensor Ground circuit at the WSS harness connector.
    1. **If the Sensor Ground circuit voltage is reading a constant 0.0 volts** - this would indicate an open in, or short across the WSS. The WSS is the faulty.
    2. **If the Sensor Ground circuit has a constant voltage** - this indicates an open in the Sensor Ground circuit path. Disconnect the WSS and BSCM harness connectors. Check the Sensor Ground circuit for high resistance. If the Sensor Ground circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A DVOM (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

1. Check the WSS harness connector for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the WSS harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.
2. Turn the ignition on and measure the voltage across the WSS (+) and WSS (-) circuits at the WSS harness connector. If both circuits are good there should be voltage present.
    1. If the voltage reads above 10.0 volts, the BSCM and circuits are testing good. Wiggle test the wiring while monitoring the voltage to check for an intermittent connection. If the voltage is steady above 10.0 volts, the Wheel Speed Sensor is likely faulty. Replace the Wheel Speed Sensor and verify repair.
    2. If no voltage is present, continue testing in step 3.
3. Remove the DVOM test lead from the WSS (-) circuit and connect to a good chassis ground. Measure the voltage on the WSS (+) circuit.
    1. If the voltage reads above 10.0 volts with the DVOM connected to chassis ground, the WSS (-) circuit is likely open or has high resistance between the WSS and the BSCM. If the circuit tests good (no resistance), the BSCM internal ground is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
    2. If no voltage is present on the WSS (+) circuit with the DVOM connected to chassis ground, continue testing in step 4.
4. Turn the ignition off and disconnect the BSCM harness connector. Check the WSS (+) circuit for continuity to both chassis ground and the WSS (-) circuit at the WSS harness connector.
    1. If there is continuity to either, repair the WSS (+) circuit for a short to ground or the WSS (-) circuit.
    2. If the signal circuit is not shorted, continue testing in step 5.
5. Measure the resistance of the WSS (+) circuit between the WSS harness connector and BSCM harness connector. There should be less than 3.0 Ohms of resistance.

1. If the resistance is below 3.0 Ohms, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
2. If the resistance is above 3.0 Ohms, repair the WSS (+) circuit for an open or high resistance.

C0572-MASTER CYLINDER PRESSURE SENSOR CIRCUIT HIGH

WHEN MONITORED

- This diagnostic runs continuously with the ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects a fault in the Brake Pressure Sensor signal that is received over the CAN BUS from the Anti-lock Brake System (ABS) Module.

DEFAULT ACTION

- The MIL will illuminate.
- The stop/start feature will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
HYDRAULIC CONTROL UNIT (HCU)
INTEGRATED CONTROL UNIT (ICU)
ANTI-LOCK BRAKE SYSTEM (ABS) MODULE

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
   1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

      Are there any applicable Service Bulletins or Flash updates?

      Yes

      - Perform the applicable repair.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
   1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
   2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
   3. With the scan tool, erase all DTCs.
   4. Turn the ignition off for a minimum of 10.0 seconds.

5. Turn the ignition on.
6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- This is a informational DTC indicating a fault is set in the Antilock Brake System (ABS) Module. Perform the appropriate diagnostic procedure(s). Refer to **ANTILOCK BRAKE SYSTEM (ABS) - DIAGNOSTIC CODE INDEX** .

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

C10F5-BRAKE TORQUE PERFORMANCE

For a complete BRAKE SYSTEM wiring diagram, **refer to the appropriate wiring information** .

DESCRIPTION AND OPERATION-BRAKING SYSTEMS

GENERAL NON-eBOOSTER BRAKING SYSTEM OPERATION: The Integrated Control Unit (ICU) consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The BSCM monitors the signal from the Brake Pedal Position (BPP) Sensor mounted on the Brake Pedal assembly and Master Cylinder Pressure (MCP) Sensor signal, mounted inside the HCU to detect when the Brake Pedal is applied. The BSCM also monitors the pressure sensors in each hydraulic circuit to calculate the Brake Torque signal. The calculation is based on the sum of pressure applied to the caliper in each hydraulic circuit. These signals are broadcast on the CAN bus. When the BSCM receives an autonomous brake input it controls a motor/actuator inside the Hydraulic Assembly to apply hydraulic pressure to the calipers to brake the vehicle.

GENERAL eBOOSTER BRAKING SYSTEM OPERATION: The Electronic Booster (eBooster) system consists of the Brake System Control Module (BSCM) and Hydraulic Control Unit (HCU). The system does not use a conventional Master Cylinder mounted on the booster. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. To maintain normal Brake Pedal feel, when the Brake Pedal is pressed it creates hydraulic pressure in a fluid filled chamber inside the HCU. The pressure acts on a cap and spring inside the chamber allowing the pedal to get firm. This system uses a Brake Pedal Simulator Pressure Sensor in place of the MCP Sensor and two unique Brake Pedal Position (BPP) Sensors to monitor for an operator braking input. The BSCM monitors these and other inputs, and controls a motor/actuator inside the HCU to apply hydraulic pressure to the calipers during an operator braking input or autonomous braking event.

NOTE:	If the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.

WHEEL SPEED SENSOR OPERATION: Wheel Speed Sensors (WSS) are used to monitor vehicle speed and wheel slip conditions. The Wheel Speed Sensors are hard-wired to the Brake System Control Module. The BSCM broadcasts the WSS signals on the CAN bus. The BSCM performs circuit fault diagnostics for the WSS sensors and wiring. The BSCM and PCM perform rationality checks against the outputs from the sensors. **This is described in detail in the DIAGNOSTIC OVERVIEW information below.** The WSS signals are also compared to the Steering Wheel Angle and Dynamic Sensors. Comparing these signals together can determine when the vehicle is in a turning event or if there is a fault in one of the WSS signals.

ANTI-LOCK BRAKING EVENT: During a braking event, the BSCM monitors the WSS signals to detect a wheel lock condition due to a skid event. If a wheel is determined to be locked, the BSCM cycles the Outlet Valve. Cycling the valve off/on relieves and applies the pressure to the wheel to correct the condition. The pressure will be regulated until the wheel lock condition is no longer present.

TRACTION CONTROL AND ELECTRONIC STABILITY CONTROL (ESC): If a wheel spin condition is detected during driving, and the brakes are not being applied, the BSCM will cycle the Inlet Valve in the system, applying braking to the wheel to correct the wheel slip condition. The system monitors the steering wheel angle, yaw rate and lateral acceleration (Dynamic Sensor) and Wheel Speed Sensors to determine an over/under steer condition. The BSCM will open the appropriate Inlet Valves, applying braking to counteract the condition.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE PEDAL POSITION SENSOR

NON-eBOOSTER SYSTEMS: 3-Wire Position Sensor - The Non-eBooster systems use a single Brake Pedal Position Sensor mounted on the Brake Pedal assembly. The BSCM provides the sensor with a 5-Volt reference, a pull down signal and sensor ground circuit. Using a pull down signal means that there will be 0 volts on the signal circuit when the connector is unplugged. The sensor is hard-wired to the BSCM. The BSCM converts the analog voltage signal to a digital signal and broadcasts it on the CAN bus. When the pedal is not pressed, the signal voltage is low. As the driver presses on the Brake Pedal, the voltage on the signal increases. The Minimum (Not pressed) and maximum (Pedal fully pressed) thresholds for the sensors are learned into the BSCM and PCM. **These thresholds must be re-learned using the scan tool every time a sensor, BSCM or PCM is replaced. If these thresholds are not learned, a performance fault will set.**

eBOOSTER SYSTEMS: Single Edge Nibble Transmission (SENT) Sensors - The eBooster system uses two SENT interface protocol sensors used to detect brake pedal travel. These sensors are internal to the Hydraulic Control Unit assembly. As the driver presses on the Brake Pedal, the Brake Pedal Position Sensors send an output only digital signal to the BSCM in percentage of travel. These sensors consist of three circuits, a power supply and ground circuit to function, and a digital output signal circuit. The power supply range is typically between 4.75 and 5.25 volts.

COMPONENT FUNCTIONAL DESCRIPTION - HYDRAULIC CONTROL UNIT (HCU) ASSEMBLY

The HCU Assembly internal components are slightly different depending on the brake system. The functionality of applying the brakes is also different. During an Anti-lock braking, traction control or stability control event, the functionality of the systems is relatively the same.

- **NON-eBOOSTER SYSTEMS:** The HCU on this system incorporates a Master Cylinder Pressure (MCP) Sensor, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The Brake Pedal Position Sensor is external, but hard-wired to the BSCM. The BSCM in this system is capable of operating the motor/actuator inside the HCU to apply the brakes during an autonomous braking event. The vehicle operator can directly brake the vehicle by pressing on the Brake Pedal.
- **eBOOSTER SYSTEMS:** The HCU on this system incorporates a Brake Pedal Simulator Pressure Sensor, two Brake Pedal Position (BPP) Sensors, motor/actuator, hydraulic circuit pressure sensors, Inlet Valves and Outlet Valves. The BSCM in this system operates the motor/actuator to apply the brakes during both vehicle operator input and autonomous braking events. During normal operation there is no direct link between the Brake Pedal and the hydraulic circuits to the calipers. However, if the BSCM is not able to monitor the Brake Pedal travel or pressure due to a fault in the system, a bypass valve is opened in the chamber which allows a direct connection between the hydraulic pressure in the chamber and the hydraulic circuits to the calipers.

The Inlet Valves allow the fluid and hydraulic pressure to the calipers in each hydraulic circuit. The Outlet Valves are used to relieve the pressure in each circuit. There are two pressure sensors located in each hydraulic circuit that allow the BSCM to monitor the pressure in the system for each circuit.

COMPONENT FUNCTIONAL DESCRIPTION - WHEEL SPEED SENSORS

The Wheel Speed Sensors can be a magnetic pickup type or Hall Effect type sensor depending on the system being used. Each system uses a different type of target. The BSCM provides a signal voltage to the sensor and a ground path. The signal voltage can be 5v or 12v depending on the system.

- The system with magnetic pickup type sensors typically use a metal tone wheel that can be mounted on the hub/bearing assembly or front axle shaft. The tone wheel will have high and low spots equally spaced around the tone wheel. As the wheel is turning the high/low spots on the tone wheel pass the magnet in the sensor causing a square wave 5v or 12v signal.
- The system with Hall Effect sensors use a magnetic pole encoder that is typically incorporated in the wheel bearing assembly. With this system the air gap between the WSS and encoders is not adjustable. As the wheel is turning the magnets in the encoder pass the Hall Effect sensor causing a square wave 5v or 12v signal.

The PCM uses the Wheel Speed Sensor signals and Steering Angle Sensor signal for Engine Stop/Start enabling and oil aeration detection. The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the wheel speed signals are showing vehicle speed present, the PCM will disable ESS mode.
- If the vehicle is in a hard turning event, as determined by the wheel speed signals the oil can be dispersed to one side of the oil pan away from the pickup tube on some vehicles. This can cause oil aeration and affect the valve timing performance fault detection. During a hard turning event the valve timing performance diagnostics will be suspended until the event ends.

COMPONENT FUNCTIONAL DESCRIPTION - STEERING ANGLE SENSOR

Depending on the vehicle, the Steering Angle Sensor (SAS) can be mounted on the Steering Column, or incorporated into the Steering Column Control Module (SCCM) or Steering Gear. The SAS signal is broadcast on the CAN bus. The SAS signal is used by several modules to monitor the Steering Wheel position and rate of change for vehicle stability control, Engine Stop/Start enabling and autonomous operations.

The PCM rationalizes the Wheel Speed Sensor signals against each other and uses the Wheel Speed Sensor signals to rationalize the Steering Angle Sensor signal.

- If the steering angle input is high (wheel turned) when the vehicle comes to a stop, and the vehicle is equipped with Electric Power Steering, the PCM will disable ESS mode. The Electric Power Steering can draw Battery voltage down quickly if the wheel is turned significantly and the engine is turned off.

COMPONENT FUNCTIONAL DESCRIPTION - BRAKE SYSTEM CONTROL MODULE (BSCM)

The BSCM is bolted to the Hydraulic Assembly. The BSCM monitors several inputs used for normal vehicle braking as well as detection and operation of anti-lock braking, traction, and electronic stability controls. The signals that are monitored are listed below. The BSCM directly monitors the signals for operating the:

- Brake Pedal Position Sensor(s)
- Master Cylinder Pressure Sensor (non-eBooster System)
- Brake Pedal Simulator Pressure Sensor (eBooster System)
- Hydraulic pressure sensors in each hydraulic circuit
- Wheel Speed Sensors
- Steering Angle Sensor
- Dynamic Sensor

These inputs are used to control the following output devices:

- Motor/actuator
- Hydraulic pump
- Inlet Check Valves

- Outlet Check Valves

TECHNICAL DATA-BRAKING SYSTEM MESSAGES

NON-eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM broadcasts the BPP Sensor signal voltage on the CAN bus. If the sensor signal is faulty, the BSCM sets a fault against the sensor and sends a Signal Not Available (SNA) message on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Master Cylinder Pressure Signal	Actual hydraulic pressure in the Master Cylinder	If the Master Cylinder Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends an SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Torque Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal is broadcast on the CAN bus.

eBOOSTER SYSTEM SIGNALS

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
MESSAGE	**MESSAGE DESCRIPTION**	**MESSAGE DEFINITION**
Brake Pedal Position Signal	Percentage of pedal travel	The BSCM sends the average of the two BPP Sensor signal inputs on the CAN bus. If one sensor is faulted, the BSCM sets a fault against the sensor and sends the input from only the good sensor on the CAN bus. The PCM will function normally if only one sensor is faulty. If both sensors are faulty, the BSCM sets a fault against both sensors and sends a Signal Not Available (SNA) signal on the CAN bus. The PCM will set the missing message fault (U11BF) for the SNA message.
Brake Pedal Pressure Signal	Simulated Brake Pedal applied pressure	If the Brake Pedal Simulator Pressure Sensor is faulty, the BSCM sets a fault against the sensor and sends and SNA message on the CAN bus. The PCM will set the implausible data fault (U0418) for the SNA message.
Brake Boost Pressure Signal	Hydraulic line pressure in the braking system to the wheels	The BSCM calculates the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. The signal broadcast on the CAN bus.
BSCM Readiness Flag	Informs PCM that ESS can be performed.	The BSCM sends an ESS readiness flag (TRUE) message when the BSCM

Brake signal messages broadcast by the Brake System Control Module (BSCM)		
		determines that ESS can be enabled. This is based on hydraulic pressure to the calipers and road grade calculation.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

Performance Faults (P057B/C053D/C10F5):

- With the ignition on.
- Battery voltage above 10.4 volts.
- No Loss of Communication or implausible/missing message faults active.

Communication Faults (U0121/U0129/U0418/U11BF):

- With the ignition on.
- Battery voltage above 10.4 volts.

Wheel Speed Sensor Signal and Distance Faults (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418):

- With the ignition on.
- Battery voltage between 9.0 and 16.0 volts.

SET CONDITION

- **C053D** - The PCM determines that the Master Cylinder Pressure Sensor signal is irrational.
- **C10F5** - The PCM determines that the Brake Torque signal is irrational.
- **P057B** - The PCM determines that the Brake Pedal Position Sensor signal is irrational.
- **U0121** - The PCM does not receive the Brake Pedal Position Sensor signal.
- **U0129** - The PCM does not receive the Master Cylinder Pressure Sensor signal.
- **U0418** - The PCM receives an SNA message indicating that the has detected a fault in the Master Cylinder Pressure Sensor signal.
- **U11BF** - The PCM receives an SNA message indicating that the has detected a fault in the Brake Pedal Position Sensor signal.
- **(C0501, C0507, C050D, C0513) Wheel Speed Signal Rationality Faults** - When at a stop, one WSS signal is showing vehicles speed output and the other three WSS signals are reading 0 OR When the difference between one WSS signal compared to the other three WSS signals is more than 11 MPH, for 30 seconds.
- **(U1409, U140A, U140B, U140C, U1412, U1417, U1418) Implausible Wheel Speed and Distance Signal Faults** - These faults will typically set when the BSCM detects a fault with one of the WSS signals. The BSCM will send an SNA or error flag against the sensor.

The (P057B, P057C, P057D, U11BF) BPP Sensor faults can set for any of the following:

DEFAULT ACTION

- The MIL will illuminate.
- ESS System is disabled.

POSSIBLE CAUSES

POSSIBLE CAUSES
5-VOLT SUPPLY CIRCUIT OPEN OR SHORTED TO GROUND
BPP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH)
BPP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW)
BPP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
BPP SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT LOW)
FAULTY BRAKE PEDAL POSITION SENSOR
FAULTY BRAKE SYSTEM MODULE (BSM)

The (C053D, C10F5, U0418) performance and implausible/lost message faults can set for any of the following:

POSSIBLE CAUSES
FAULTY HYDRAULIC ASSEMBLY (BPP AND BRAKE SIMULATOR SENSORS ARE INTERNAL)
FAULTY BRAKE SYSTEM MODULE (BSM)

The (U0121, U0129) Loss of Communication faults can set for any of the following:

POSSIBLE CAUSES
BATTERY OR IGNITION SUPPLY TO BSM OPEN OR SHORTED TO GROUND
BSM GROUND CIRCUIT OPEN/HIGH RESISTANCE
BSM CAN BUS CIRCUITS SHORTED TO VOLTAGE
BSM CAN BUS CIRCUITS SHORTED TO GROUND
BSM CAN BUS CIRCUITS OPEN/HIGH RESISTANCE
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

The Wheel Speed Sensor faults can set for any of the following:

POSSIBLE CAUSES
SNA OR ERROR MESSAGE FROM BSCM
WSS SIGNAL CIRCUITS SHORTED TO VOLTAGE
WSS SIGNAL CIRCUITS SHORTED TO GROUND
WSS SIGNAL CIRCUITS OPEN/HIGH RESISTANCE
WSS GROUND CIRCUIT OPEN/HIGH RESISTANCE
DAMAGED TONE WHEEL
FAULTY WHEEL SPEED SENSOR
FAULTY BRAKE SYSTEM CONTROL MODULE (BSCM)

DIAGNOSTIC OVERVIEW

NON-eBOOSTER SYSTEM: When any faults are present against the BPP Sensor in the BSCM or PCM, the sensor and circuits should always be checked before condemning a module. While the Master Cylinder Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an ICU assembly.

eBOOSTER SYSTEM: While the BPP Sensors, Brake Pedal Simulator Pressure Sensor and hydraulic circuit pressure sensors are inside the HCU, the connection between the HCU and BSCM should always be checked for proper connection, burnt, corroded or damaged terminals before condemning the HCU. If the BSCM is found to be the issue it can be replaced separately. If the HCU is determined to be the issue, the HCU and BSCM should be replaced as an eBooster assembly.

WHEEL SPEED SENSORS: When the vehicle is moving, the Wheel Speed Sensor signals are rationalized against each other for a stuck sensor. The controller is able to determine difference between a fault and a normal vehicle turning event (explained below).

WHEEL SPEED SENSOR COMPARISONS MONITORED	
Left Front vs Right Front	LF/RF
Left Front vs Left Rear	LF/LR
Left Front vs Right Rear	LF/RR
Right Front vs Left Rear	RF/LR
Right Front vs Right Rear	RF/RR
Left Rear vs Right Rear	LR/RR

The **enable condition threshold** is used as the comparison threshold. The threshold is calculated by taking the average of the six comparison calculations in the table when the vehicle is moving.

- **Driving Straight** - When the vehicle is moving in a straight line (steering wheel angle is near zero) the four sensor signal outputs should be relatively equal. If the LF sensor was stuck, the difference in the three calculations between the LF and other three sensors (LF/RF, LF/LR, LF/RR) will be above the enable condition threshold and the other three calculations (RF/LR, RF/RR, LR/RR) will be below the enable condition threshold, indicating a LF Wheel Speed Sensor failure.
- **Turning** - When the vehicle is turning all of the comparison checks will be different. The differences for all of the comparison checks will increase as the turning radius increases. If all comparison checks are above the calculated enable condition threshold, the vehicle is considered to be in a significant turning event and the diagnostic is temporarily disabled.
- **Vehicle Stopped** - When the vehicle is stopped each Wheel Speed Sensor signal should be 0. If three sensor outputs equal 0 and the forth is above 0 for a calibrated period threshold, the sensor is determined to be irrational.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.
2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connection issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways.

Check the Battery or Batteries for proper charge and operation along with proper connections. Use the appropriate wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.

4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

DIAGNOSTIC TEST - NON-EBOOSTER BRAKE SYSTEM - PCM

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

BRAKE PEDAL POSITION SENSOR CIRCUIT FAULTS (P057C, P057D): TECH TIP: Typical three wire sensors must have voltage present on the 5-Volt Supply circuit to function properly. No voltage on the 5-Volt Supply circuit can cause the sensor to react one of two ways, depending on the type of sensor being used. The first is the sensor signal voltage can be stuck mid range (2.4-2.6 volts), and not change which can cause a performance fault. The second is the signal voltage can be stuck low (0 volts) since the ECU is using a pull-down signal.

1. Check the sensor harness connector for proper connection at the BPP Sensor. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the BPP Sensor harness connector and check for any pushed out, damaged, corroded or spread terminals.
2. Measure the voltage on the 5-Volt Supply circuit with the ignition on. The voltage should measure above 4.9 volts.
    1. If voltage is present, continue to step 3.
    2. If no voltage is present at the harness connector, repair the 5-Volt Supply circuit for an open or high resistance.
3. This step is designed to determine if the fault is being caused by a faulty sensor. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the BPP Sensor signal and 5-Volt Supply circuit at the BPP Sensor harness connector. A fused jumper can also be used for this step. Move the switch on the Electrical Test Lead Kit to the CLOSED position while either monitoring the voltage or fault screen on the scan tool. The voltage should read 5.0v if available, or the circuit high fault should be active. Next, connect the leads between the signal circuit and the sensor circuit at the BPP Sensor harness connector. The voltage should read 0v if available, or the circuit low fault should be active.

NOTE: **Since the BSCM uses a pull down signal, simply disconnecting the sensor harness connector should also give the same results.**

1. If the voltage or faults appear as described above, the BPP Sensor is most likely faulty.
2. If the voltage remains at 0v and only the circuit low fault is active, continue to step 4.

4. Disconnect the BSCM harness connector to isolate the circuits and check the sensor signal circuit for continuity to both chassis ground and the sensor ground circuit.
    1. If there is continuity to either, repair the signal circuit for a short to chassis ground or the sensor ground circuit.
    2. If the signal circuit is not shorted, continue to step 5.
5. Measure the resistance of the sensor signal and sensor ground circuits. Typically the circuit resistance should be less than 5.0 Ohms.
    1. If there is an open or high resistance in either circuit, repair the signal circuit for an open or high resistance.
    2. If the temp sensor signal and ground circuits test good, Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning BSCM. If no issues are found, replace the BSCM in accordance with the service information.

PCM SYSTEM PERFORMANCE FAULTS (P057B, C053D, C10F5): The signal performance faults set when one of the following signals received from the BSCM is irrational when compared to the others. The rationality checks are only done during a driver initiated braking event, not during an autonomous braking event.

- P057B - Brake Pedal Position signal is irrational.
- C053D - Master Cylinder Pressure signal is irrational.
- C10F5 - Brake Torque signal is irrational.

The Master Cylinder Pressure Sensor is internal to the Hydraulic Control Unit (HCU). The Brake Torque signal is calculated by the BSCM. The calculation is based on the sum of the hydraulic pressure to the calipers in all four hydraulic circuits. If one of these signals is irrational, the HCU or BSCM are likely faulty.

1. If the P057B fault is present, perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).

- If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
- If the BSCM and terminals appear good, replace the eBooster assembly in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM IMPLAUSIBLE DATA FAULT (U11BF): The lost brake signal fault sets when the BSCM detects a fault against the Brake Pedal Pressure Sensor and has no rational signal to send to the PCM.

1. There should be a circuit fault set in the PCM, BSCM or both. Perform the circuit fault diagnostics for the BPP Sensor before continuing to step 2.
2. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
   - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
   - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM IMPLAUSIBLE DATA FAULT (U0418): The implausible data fault sets when the BSCM detects a fault against the Master Cylinder Pressure Sensor and has no rational signal to send to the PCM.

1. Verify the BSCM is mounted correctly to the HCU. Next, remove the BSCM and inspect the terminals for signs of damage (pushed out, spread, corroded or dirty terminals).
   - If the BSCM terminals appear damaged, repair the terminals or replace the BSCM in accordance with the Service Information.
   - If the BSCM and terminals appear good, replace the HCU in accordance with the Service Information.

NOTE: **The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.**

PCM LOSS OF COMMUNICATION FAULTS (U0121, U0129): The U0121 fault sets when the PCM does not receive the Brake Pedal Position Sensor signal message from the BSCM and the U0129 fault sets when the PCM does not receive the Master Cylinder Pressure Sensor signal message. Perform the following diagnostic checks for the Brake System Control Module:

1. Check for any Service Bulletins, Star On-line Cases, PCM or BSCM flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause a DTC.
3. Verify the vehicle modules are configured correctly. An incorrect configuration can cause a Loss of Communication fault.

4. Using the wiring information as a guide, check the fuse or fuses that supply power to BSCM. Verify the fuse(s) are not open and has a good connection with the terminals in the PDC
    1. If the fuse(s) are good, continue testing in step 5.
    2. If a fuse is open, check the supply circuit for a short to ground before replacing the fuse.
5. 
   Disconnect the BSCM harness connector and load test the Battery Supply and Ignition circuits.

    1. A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to **CIRCUIT LOAD TESTING PROCEDURES** .
    2. To verify that there is no resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. The voltage drop across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.
        - If either circuit fails the load testing, repair the resistance in the circuit. If the fuse that supplies power to the module is open or damaged
        - If both circuits pass the load test, continue testing in step 6.
6. 
   Load test the BSCM Ground circuit.

    1. If the ground circuit fails load testing, repair the BSCM chassis ground.
    2. If the ground circuit tests good, continue testing in step 7.
7. Check the voltage on the CAN Bus (+) and CAN Bus (-) circuits at the BSCM. Typically the CAN Bus (+) voltage should be approximately 2.6v and CAN Bus (-) voltage should be approximately 2.4v.
    1. If the voltage readings do not match the values given above, check the suspect circuit for opens or shorts.

NOTE: **A short in a Bus circuit would likely cause a Bus Performance fault or affect several modules. If only one module has Loss of Communication faults logged against it due to a wiring issue, it would likely be due to an open in a Bus circuit in the module harness connector or the wiring leading to that module.**

2. If both voltage readings match the values given, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the BSCM. To check for an intermittent condition, connect a lab scope to both circuits at the BSCM connector and wiggle test to the wiring harnesses monitoring for a drop in either Bus circuit. If no issues are found, replace the BSCM in accordance with the service information.

The HCU and BSCM are separate components, but may be required to be replaced as an Integrated Control Unit (ICU) for a period of time on some vehicles. If the BSCM is suspected to be the failure, always check to see if the BSCM can be replaced separately. If the HCU is suspected, the entire ICU should be replaced.

DIAGNOSTIC TEST-WHEEL SPEED SENSOR FAULTS

PCM RELATED WHEEL SPEED SENSOR SIGNAL FAULTS (C0501, C0507, C050D, C0513, U1409, U140A, U140B, U140C, U1412, U1417, U1418)

BSCM RELATED WHEEL SPEED SENSOR FAULTS - The BSCM performs the following diagnostic checks on the Wheel Speed Sensors

- Signal circuit continuity check (C0031-1D, C0034-1D, C0036-1D, C0037-1D)
- Erratic signal check (C0031-2F, C0034-2F, C0036-2F, C0037-2F)
- Incorrect component installed check - (C0031-4A, C0034-4A, C0036-4A, C0037-4A) - front and rear sensors are not compatible on some vehicles.
- Rationality check (C0031-62, C0034-62, C0036-62, C0037-62)

PRELIMINARY DIAGNOSTIC CHECKS

1. Check the tire and wheel sizes. Mismatched tires and wheels can cause rationality DTCs to set.
2. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
3. Check for any Battery voltage DTCs in the BSCM. Low Battery voltage can cause DTCs.
4. Circuit faults should typically be diagnosed before rationality/performance faults.

DIAGNOSING AN INCORRECT COMPONENT INSTALLED FAULT IN BSCM (C0031-4A, C0034-4A, C0036-4A, C0037-4A):

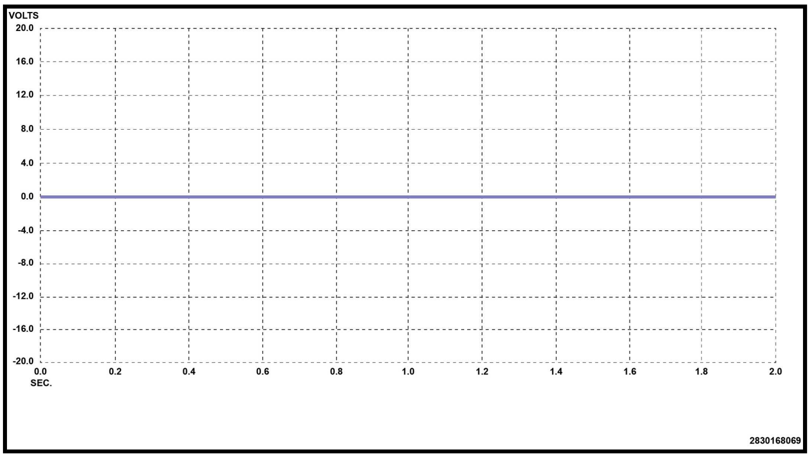
1. Some vehicles use a non-directional front WSS and directional rear WSS. The sensors are not interchangeable. Verify the correct WSS is installed on the vehicle for this fault.
   1. If the wrong part is installed, replace the WSS with the correct part number and verify repair.
   2. If the correct part is installed, replace the WSS. Clear the DTC, test drive the vehicle and confirm repair. If the DTC returns replace the Brake System Control Module in accordance with the Service Information.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A LAB SCOPE - PREFERRED METHOD (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

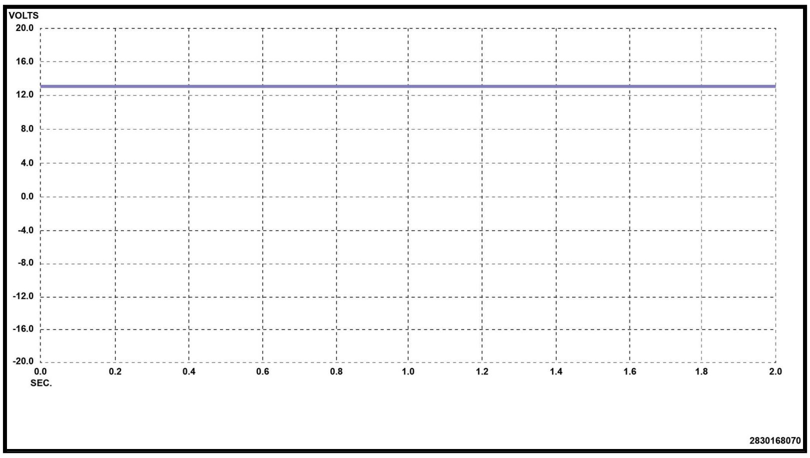
1. Turn the ignition on. At the WSS harness connector, back probe the WSS signal circuit with the lab scope test lead. The harness connector should be plugged into the WSS. Raise the vehicle on a hoist and turn the wheel while monitoring the scope signal. There should be a consistent square wave signal cycling between 0v and some voltage. The voltage may vary depending on the vehicle. The frequency of the

signal will change with the speed of the wheel but the consistency of the pattern should not. While turning the wheel watch the signal closely for the following. Inconsistency in the signal (gaps too large or small) due to a defective tone wheel/encoder or a loose, damaged sensor. A signal that is stuck high or stuck low. A signal that falls off intermittently or at lower speeds. Pick the scenario that best matches the results.

1. **The square wave signal is consistently cycling** - the sensor signal is giving a legitimate reading. The WSS and wiring are performing properly. Test drive the vehicle while monitoring the sensors. If the signal is erratic or dropping off during the test drive, check the sensor, wheel bearing and hub for looseness or damage that may not be showing up on the hoist. If the sensor reads correctly during the test drive and the fault is active, the BSCM is likely faulty. Always check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.
2. **The square wave signal is cycling but has erratic gaps or periodically drops off** - All of the issues listed can cause an erratic signal.
    - Check the WSS for physical damage and verify it is mounted and fastened properly.
    - If equipped with a tone wheel, inspect the tone wheel for physical damage.
    - On vehicles with encoders check the wheel bearing and hub for a worn bearing or excessive runout.
    - If no damage is found in the WSS, tone wheel, hub or wheel bearing assembly, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent circuit issue. If no issues are found, replace the Wheel Speed Sensor and verify repair.
3. **The signal has a constant 0.0 volt reading** - this indicates that the WSS Signal circuit is shorted to ground or has an open between the BSCM and WSS. Disconnect the WSS and BSCM harness connectors. Check the WSS Signal circuit for high resistance or a short to ground. If the WSS Signal circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM.



4. **The signal reading has a constant voltage** - this indicates an open further downstream in the circuitry. Most likely the WSS or the Sensor Ground circuit. Continue testing in step 2.



2. To check the WSS, back probe and attach a scope lead to the Sensor Ground circuit at the WSS harness connector.
    1. **If the Sensor Ground circuit voltage is reading a constant 0.0 volts** - this would indicate an open in, or short across the WSS. The WSS is the faulty.
    2. **If the Sensor Ground circuit has a constant voltage** - this indicates an open in the Sensor Ground circuit path. Disconnect the WSS and BSCM harness connectors. Check the Sensor Ground circuit for high resistance. If the Sensor Ground circuit checks good, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.

PERFORMING WSS CIRCUIT FAULT DIAGNOSTICS USING A DVOM (THIS COVERS BSCM SIGNAL AND RATIONALITY FAULTS AND ANY PCM WSS FAULTS):

1. Check the WSS harness connector for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the WSS harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.
2. Turn the ignition on and measure the voltage across the WSS (+) and WSS (-) circuits at the WSS harness connector. If both circuits are good there should be voltage present.
    1. If the voltage reads above 10.0 volts, the BSCM and circuits are testing good. Wiggle test the wiring while monitoring the voltage to check for an intermittent connection. If the voltage is steady above 10.0 volts, the Wheel Speed Sensor is likely faulty. Replace the Wheel Speed Sensor and verify repair.
    2. If no voltage is present, continue testing in step 3.
3. Remove the DVOM test lead from the WSS (-) circuit and connect to a good chassis ground. Measure the voltage on the WSS (+) circuit.
    1. If the voltage reads above 10.0 volts with the DVOM connected to chassis ground, the WSS (-) circuit is likely open or has high resistance between the WSS and the BSCM. If the circuit tests good (no resistance), the BSCM internal ground is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
    2. If no voltage is present on the WSS (+) circuit with the DVOM connected to chassis ground, continue testing in step 4.
4. Turn the ignition off and disconnect the BSCM harness connector. Check the WSS (+) circuit for continuity to both chassis ground and the WSS (-) circuit at the WSS harness connector.
    1. If there is continuity to either, repair the WSS (+) circuit for a short to ground or the WSS (-) circuit.
    2. If the signal circuit is not shorted, continue testing in step 5.
5. Measure the resistance of the WSS (+) circuit between the WSS harness connector and BSCM harness connector. There should be less than 3.0 Ohms of resistance.

1. If the resistance is below 3.0 Ohms, the BSCM is likely faulty. Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals that can cause an intermittent open before condemning a BSCM. If no issues are found, the BSCM is faulty.
2. If the resistance is above 3.0 Ohms, repair the WSS (+) circuit for an open or high resistance.

P000A-BANK 1 CAMSHAFT 1 POSITION SLOW RESPONSE

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Variable Valve Timing (VVT) system continuously varies the Camshaft target position based on the engine operating parameters. Based on these parameters, the Powertrain Control Module (PCM) calculates or models the optimum Camshaft position. The Camshaft angular position is varied by the oil control valve. The VVT solenoid pushes on a plunger (spring loaded spool valve) in the center of the Oil Control Valve (OCV) which directs oil pressure to the hydraulic actuator (Phaser) on the Camshaft Sprocket to change the Camshaft position relative to the Crankshaft position. The VVT Solenoid, acting on the Oil Control Valve and Phaser, is controlled by the PCM. The Camshaft Position (CMP) Sensor is used to monitor the position of the Camshaft.

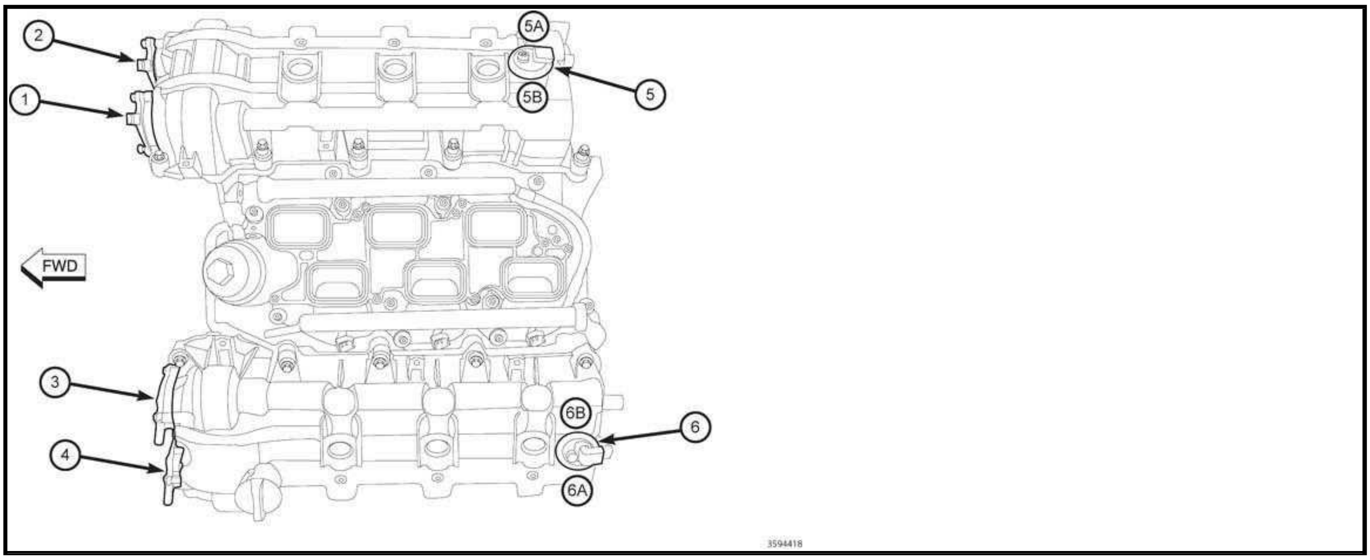
NOTE: **For the PCM to run this diagnostic the CMP Sensor and CKP Sensor signals must be locked with no sensor faults present. A missing or erratic CMP or CKP signal cannot cause a slow response fault to set. Replacing either sensor will not fix the vehicle.**

The PCM performs the typical diagnostic checks on the control circuits. During operation of the system the PCM also performs a **Target Error** and a **Slow Response** diagnostic check of the Camshaft phasing since these conditions could potentially increase tailpipe emissions. The diagnostic is primarily performed by comparing the actual Camshaft position to that of a calculated model for the Camshaft position. This diagnostic is continuous once the enable conditions are met. The Slow Response and Target Error conditions are not performed simultaneously.

- **The Target Error** diagnostic evaluates the actual Camshaft position versus the modeled position when the Camshaft is in a relatively stable position. The difference between the two is considered to be the amount of "error". If the error amount is greater than a calibrated threshold, it is considered failing.
- **The Slow Response** diagnostic is only performed when the modeled Camshaft position is moving (phasing) in a particular direction, advancing or retarding. The modeled Camshaft phasing position is created to match only the worst possible case of a passing Camshaft position. If the actual Camshaft phasing operates slower than the model by a calibrated threshold, it is considered failing.

If either of these diagnostics fail, the Camshaft Position Slow Response fault will set. **Any oil pressure issues, VVT Solenoid or Oil Pump Solenoid Control circuit faults should be diagnosed before diagnosing a Camshaft Position Slow Response fault.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft Position Slow Response that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT				
CAMSHAFT POSITION	RELATED CAM SENSOR DTCS	PHASER/ACTUATOR DTCS	MISALIGNMENT DTCS	COLD START PERF DTCS
(1) Bank 1 Intake Camshaft	P0365, P0369	P000A, P0010	P0017	P052A, P052B
(2) Bank 1 Exhaust Camshaft	P0340, P0344	P000B, P0013	P0016	P054A, P054B
(3) Bank 2 Intake Camshaft	P0390, P0394	P000C, P0020	P0019	P052C, P052D
(4) Bank 2 Exhaust Camshaft	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Engine speed is at least 650 to 1400 rpm, depending on oil temperature.
- Oil temperature is between -7Â°C to 139Â°C (19Â°F to 282Â°F).
- Battery voltage is above 10.0 volts.
- No CMP Sensor, Crankshaft Position (CKP) Sensor, or OBDI plausibility errors.
- Cam phasing is being commanded.

SET CONDITION

- The actual Camshaft position does not match the desired Camshaft position during Camshaft phasing for approximately 30.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.
- The PCM will attempt to return the Camshaft Phaser to lock pin when the fault is active.

POSSIBLE CAUSES

Possible Causes
ENGINE OIL LEVEL LOW
CAM/CRANK LEARNED VALUES OUT OF TOLERANCE
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
VVT INTAKE SOLENOID 1/1 FAULTY OR INTERMITTENTLY BINDING/STICKING
CAMSHAFT 1/1 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT TONE WHEEL MISALIGNED
CAMSHAFT 1/1 PHASER FAULTY OR INTERMITTENTLY BINDING/STICKING
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **CHECK FOR OTHER DTCS**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and Freeze Frame Data and record on the repair order.

       Are there any system voltage, Oil Pump or Camshaft Position DTCs present?

       Yes

       - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 3
3. **VERIFY THE CAM/CRANK LEARNED VALUES ARE WITHIN TOLERANCE**
    1. With the scan tool, read the Cam/Crank Difference Learned values in the Data Display.

NOTE: **When the Cam/Crank Learn is performed the Camshaft position is learned in High Lift and Low Lift modes on the Variable Valve Lift (VVL) equipped engines. The difference between the High Lift and Low Lift learned values should be less than 2Â° for each Camshaft.**

NOTE: **If the Cam/Crank Difference Learned values are not in the Data Display, go to 4.**

Are the Intake Cam 1 High Lift and Low Lift learned values within 2Â° of each other?

Yes

- Go To 4

No

- With the scan tool perform the **Cam/Crank Relearn** procedure and retest for DTC.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE ENGINE OIL/ENGINE MECHANICAL CONDITION**
   1. Turn the ignition off.
   2. The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.
      - LOW ENGINE OIL LEVEL
      - CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL
      - INCORRECT ENGINE OIL VISCOSITY
      - ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION
      - ENGINE OIL PRESSURE OUT OF SPECIFICATION
      - INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)

   Were any of the above conditions present?

   Yes

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.) in accordance with the Service Information.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5

5. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

   NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

   1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
   2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
   3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
   4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor.
   5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.

Is the oil pressure reading stable and above 16.0 psi?

Yes

- Go To 6

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE ENGINE OIL PRESSURE TO THE CYLINDER HEAD**
   1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
   2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid and install an oil pressure gauge to the adaptor.
   3. Start the engine and allow it to idle.
   4. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: The oil pressure reading at the Cylinder Head should be above 14.0 psi.

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 7

No

- Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **VERIFY AN ACTIVE CONDITION BY CHECKING THE CAM PHASER POSITION**

NOTE: If a Cam Phaser or Oil Control Valve is stuck, there may also be a Crankshaft/Camshaft Timing Misalignment and/or Multiple Cylinder Misfire DTC present.

NOTE: The Intake Camshaft is phased less frequently than the Exhaust Camshaft during engine operation. Therefore it may be necessary to test drive the vehicle under different load conditions to get enough phasing of the Intake Camshaft to duplicate the condition and check the values.

1. What to monitor for during the test step:

- **The phaser not coming back to lock pin at idle.** This his could indicate a faulty phaser or oil control valve that is permanently stuck off lock pin or a VVT Solenoid that is electrically stuck on.
- **The actual position lagging or moving slowly toward the desired position.** This could indicate a faulty phaser or tarnished oil control valve that is dragging.
- **The actual position lagging and then overshooting the desired position** This could indicate a faulty phaser, oil control valve or VVT Solenoid that is intermittently sticking or binding and then overshoot when the condition goes away.

2. Start the engine and allow the engine to idle.
3. With the scan tool, monitor and compare the Intake Cam 1 **actual** position value with the Intake Cam 1 **desired** position value. After comparing the two values at idle, check and compare the values at several different engine speeds during the following steps.
4. While monitoring the Intake Cam 1 actual position and desired position values:
   - Raise the engine speed quickly and hold steady for up to 30 seconds.
   - Lower the engine speed and hold steady at a level above idle (off of lock pin) for up to 30 seconds.
5. Repeat the above steps multiple times and allow the engine to come back to idle while monitoring the actual position value to verify that the phaser is returning to lock pin position.

   Is the difference between the actual value and the desired value readings more than 6.0 degrees at idle or is the actual value lagging behind or overshooting the desired value?

   Yes, the difference is greater than 6.0 degrees at idle indicating that the camshaft will not return to lock pin:

   - Go To 8

   Yes, the actual reading is lagging or overshooting when changing the engine speeds indicating a binding or sticking:

   - Go To 9

   No

   - This fault is occurring due to an intermittent condition. The problem could be due to an intermittent sticking or dragging condition of one of the timing components listed in the possible causes table. The issue could be temperature related (I.E. Incorrect or broken down oil affecting operation during a cold start, or a tolerance issue in a component that is affected after a cold start/heat soak or after the engine is warmed to operating temperature). The issue could also be occurring during certain specific driving conditions. It may be necessary to test drive the vehicle under different load conditions to duplicate the issue.

8. **DETERMINE IF THE CAM PHASER ISSUE IS ELECTRICAL OR MECHANICAL**
   1. While the engine is at idle, disconnect the VVT Intake Solenoid 1/1 harness connector.

      NOTE: **The Intake Cam 1 actual position value should change to lock pin with the solenoid disconnected. The Intake Cam position should be at approximately 146.0Â° at lock pin.**

      Did the Intake Cam 1 actual value change to lock pin position when the solenoid is unplugged?

      Yes

      - Check the VVT Intake Solenoid 1/1 (K76) Control circuit for a short to voltage. If the circuit is not shorted to voltage, Go To 13

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 9

9. **CHECK THE CAMSHAFT 1/1 OIL CONTROL VALVE OPERATION**
   1. Turn the ignition off.
   2. Remove the VVT Intake Solenoid 1/1.
   3. Inspect the spring loaded spool valve on the Oil Control Valve.

      NOTE: The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.

   4. Push and release the spring loaded spool valve against the return spring with a small punch.

      NOTE: The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.

   Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

   Yes

   - Go To 10

   No

   - Replace the Camshaft 1/1 Oil Control Valve in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
   - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK THE VVT INTAKE SOLENOID 1/1 OPERATION**
    1. Turn the ignition off.
    2. With the solenoid still removed, reconnect the VVT Intake Solenoid 1/1 harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the VVT Intake Solenoid 1/1 on and off several times.

    Does the VVT Intake Solenoid 1/1 move freely without binding or sticking during actuation?

    Yes

    - Go To 11

    No

    - Replace the VVT Intake Solenoid 1/1 in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **VERIFY THAT THE VVT INTAKE SOLENOID 1/1 IS ABLE TO MOVE THE PHASER**
    1. Exchange the VVT Intake Solenoid 1/1 with the other VVT Intake Solenoid 2/1.

       NOTE: **The Intake and Exhaust Solenoids should not be interchanged.**

    2. Reconnect the solenoid harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs in the PCM.
    5. Test drive the vehicle under the conditions in which the fault was set.
    6. With the scan tool, read DTCs.

    Did the DTC move with the solenoid or stay with the original camshaft?

    Moved with the solenoid

    - Replace the VVT Intake Solenoid 1/1 in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    Stayed with the original camshaft

    - Go To 12

12. **CHECK THE INTAKE CAMSHAFT 1/1 TONE WHEEL**
    1. Turn the ignition off.
    2. Check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Is the CMP Sensor Tone Wheel aligned correctly?

    Yes

    - Replace the Cam 1/1 Phaser in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Replace the Intake Camshaft Assembly in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

DIAGNOSIS AND TESTING

P000B-BANK 1 CAMSHAFT 2 POSITION SLOW RESPONSE

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Variable Valve Timing (VVT) system continuously varies the Camshaft target position based on the engine operating parameters. Based on these parameters, the Powertrain Control Module (PCM) calculates or models the optimum Camshaft position. The Camshaft angular position is varied by the oil control valve. The VVT solenoid pushes on a plunger (spring loaded spool valve) in the center of the Oil Control Valve (OCV) which directs oil pressure to the hydraulic actuator (Phaser) on the Camshaft Sprocket to change the Camshaft position relative to the Crankshaft position. The VVT Solenoid, acting on the Oil Control Valve and Phaser, is controlled by the PCM. The Camshaft Position (CMP) Sensor is used to monitor the position of the Camshaft.

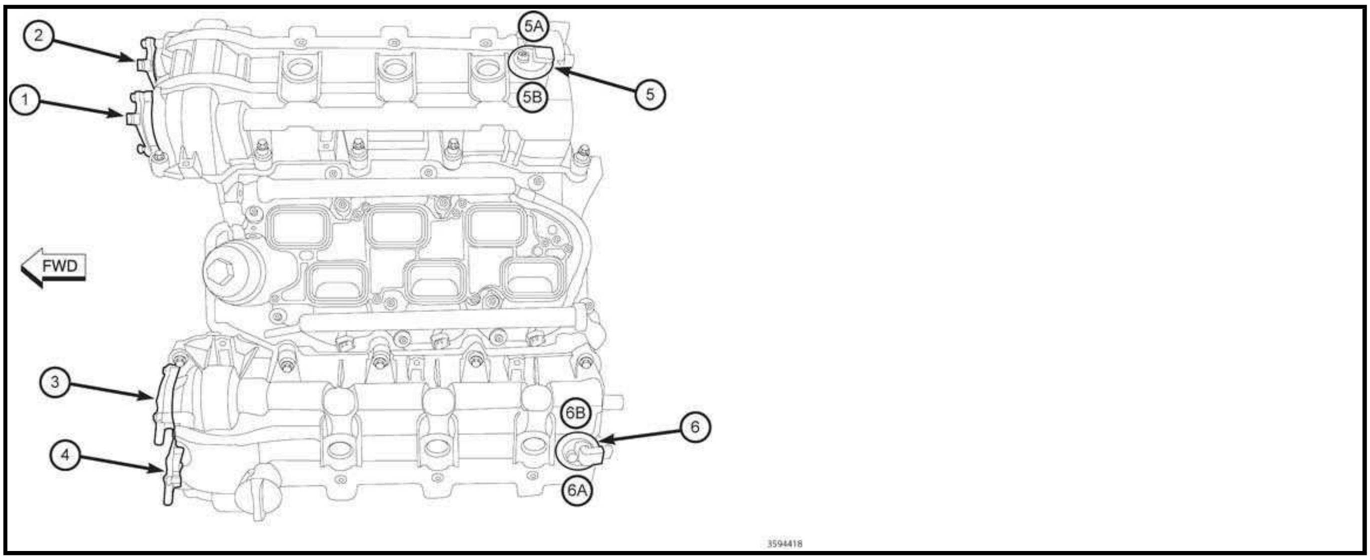
NOTE: **For the PCM to run this diagnostic the CMP Sensor and CKP Sensor signals must be locked with no sensor faults present. A missing or erratic CMP or CKP signal cannot cause a slow response fault to set. Replacing either sensor will not fix the vehicle.**

The PCM performs the typical diagnostic checks on the control circuits. During operation of the system the PCM also performs a **Target Error** and a **Slow Response** diagnostic check of the Camshaft phasing since these conditions could potentially increase tailpipe emissions. The diagnostic is primarily performed by comparing the actual Camshaft position to that of a calculated model for the Camshaft position. This diagnostic is continuous once the enable conditions are met. The Slow Response and Target Error conditions are not performed simultaneously.

- **The Target Error** diagnostic evaluates the actual Camshaft position versus the modeled position when the Camshaft is in a relatively stable position. The difference between the two is considered to be the amount of "error". If the error amount is greater than a calibrated threshold, it is considered failing.
- **The Slow Response** diagnostic is only performed when the modeled Camshaft position is moving (phasing) in a particular direction, advancing or retarding. The modeled Camshaft phasing position is created to match only the worst possible case of a passing Camshaft position. If the actual Camshaft phasing operates slower than the model by a calibrated threshold, it is considered failing.

If either of these diagnostics fail, the Camshaft Position Slow Response fault will set. **Any oil pressure issues, VVT Solenoid or Oil Pump Solenoid Control circuit faults should be diagnosed before diagnosing a Camshaft Position Slow Response fault.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft Position Slow Response that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT				
CAMSHAFT POSITION	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERF DTCS**

(4) Bank 2 Exhaust Camshaft	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Engine speed is at least 650 to 1400 rpm, depending on oil temperature.
- Oil temperature is between -7B°C to 139B°C (19B°F to 282B°F).
- Battery voltage is above 10.0 volts.
- No CMP Sensor, Crankshaft Position (CKP) Sensor, or OBDI plausibility errors.
- Cam phasing is being commanded.

SET CONDITION

- The actual Camshaft position does not match the desired Camshaft position during Camshaft phasing for approximately 30.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.
- The PCM will attempt to return the Camshaft Phaser to lock pin when the fault is active.

POSSIBLE CAUSES

Possible Causes
ENGINE OIL LEVEL LOW
CAM/CRANK LEARNED VALUES OUT OF TOLERANCE
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
VVT EXHAUST SOLENOID 1/2 FAULTY OR INTERMITTENTLY BINDING/STICKING
CAMSHAFT 1/2 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT TONE WHEEL MISALIGNED
CAMSHAFT 1/2 PHASER FAULTY OR INTERMITTENTLY BINDING/STICKING
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **CHECK FOR OTHER DTCS**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and Freeze Frame Data and record on the repair order.

       Are there any system voltage, Oil Pump or Camshaft Position DTCs present?

       Yes

       - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 3
3. **VERIFY THE CAM/CRANK LEARNED VALUES ARE WITHIN TOLERANCE**
    1. With the scan tool, read the Cam/Crank Difference Learned values in the Data Display.

NOTE:	When the Cam/Crank Learn is performed the Camshaft position is learned in High Lift and Low Lift modes on the Variable Valve Lift (VVL) equipped engines. The difference between the High Lift and Low Lift learned values should be less than 2B° for each Camshaft.

NOTE: **If the Cam/Crank Difference Learned values are not in the Data Display, go to 4.**

Are the Exhaust Cam 1 High Lift and Low Lift learned values within 2B° of each other?

Yes

- Go To 4

No

- With the scan tool perform the **Cam/Crank Relearn** procedure and retest for DTC.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE ENGINE OIL/ENGINE MECHANICAL CONDITION**
    1. Turn the ignition off.

NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

- **LOW ENGINE OIL LEVEL**
- **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL**
- **INCORRECT ENGINE OIL VISCOSITY**
- **ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION**
- **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

Were any of the above conditions present?

Yes

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.) in accordance with the Service Information.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.

4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

Is the oil pressure reading stable and above 16.0 psi?

Yes

- Go To 6

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE ENGINE OIL PRESSURE TO THE CYLINDER HEAD**
   1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
   2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid and install an oil pressure gauge to the adaptor.
   3. Start the engine and allow it to idle.
   4. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 7

No

- Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **VERIFY AN ACTIVE CONDITION BY CHECKING THE CAM PHASER POSITION**

NOTE: **If a Cam Phaser or Oil Control Valve is stuck, there may also be a Crankshaft/Camshaft Timing Misalignment and/or Multiple Cylinder Misfire DTC present.**

   1. What to monitor for during the test step:

        - **The phaser not coming back to lock pin at idle.** This his could indicate a faulty phaser or oil control valve that is permanently stuck off lock pin or a VVT Solenoid that is electrically stuck on.
        - **The actual position lagging or moving slowly toward the desired position.** This could indicate a faulty phaser or tarnished oil control valve that is dragging.
        - **The actual position lagging and then overshooting the desired position** This could indicate a faulty phaser, oil control valve or VVT Solenoid that is intermittently sticking or binding and then overshoot when the condition goes away.
    2. Start the engine and allow the engine to idle.
    3. With the scan tool, monitor and compare the Exhaust Cam 1 **actual** position value with the Exhaust Cam 1 **desired** position value. After comparing the two values at idle, check and compare the values at several different engine speeds during the following steps.
    4. While monitoring the Exhaust Cam 1 actual position and desired position values:
        - Raise the engine speed quickly and hold steady for up to 30 seconds.
        - Lower the engine speed and hold steady at a level above idle (off of lock pin) for up to 30 seconds.
    5. Repeat the above steps multiple times and allow the engine to come back to idle while monitoring the actual position value to verify that the phaser is returning to lock pin position.

       Is the difference between the actual value and the desired value readings more than 6.0 degrees at idle or is the actual value lagging behind or overshooting the desired value?

       Yes, the difference is greater than 6.0 degrees at idle:

        - Go To 8

       Yes, the actual reading is lagging or overshooting when changing the engine speeds indicating a binding or sticking:

        - Go To 9

       No

        - This fault is occurring due to an intermittent condition. The problem could be due to an intermittent sticking or dragging condition of one of the timing components listed in the possible causes table. The issue could be temperature related (I.E. Incorrect or broken down oil affecting operation during a cold start, or a tolerance issue in a component that is affected after a cold start/heat soak or after the engine is warmed to operating temperature). The issue could also be occurring during certain specific driving conditions. It may be necessary to test drive the vehicle under different load conditions to duplicate the issue.
8. **DETERMINE IF THE CAM PHASER ISSUE IS ELECTRICAL OR MECHANICAL**
    1. While the engine is at idle, disconnect the VVT Exhaust Solenoid 1/2 harness connector.
    2. The Exhaust Cam 1 actual position value should change to lock pin with the solenoid disconnected. The Exhaust Cam position should be at approximately 123.0 degrees at lock pin.

       Did the Exhaust Cam 1 actual value change to lock pin position with the solenoid unplugged?

       Yes

        - Check the (K276) VVT Exhaust Control 1/2 circuit for a short to voltage. If the circuit is not shorted to voltage, Go To 13
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

- Go To 9

9. **CHECK THE CAMSHAFT 1/2 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.
    2. Remove the VVT Exhaust Solenoid 1/2.
    3. Inspect the spring loaded spool valve on the Oil Control Valve.

       NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

    4. Push and release the spring loaded spool valve against the return spring with a small punch.

       NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

    Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

    Yes

    - Go To 10

    No

    - Replace the Camshaft 1/2 Oil Control Valve in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK THE VVT EXHAUST SOLENOID 1/2 OPERATION**
    1. Turn the ignition off.
    2. With the solenoid still removed, reconnect the VVT Exhaust Solenoid 1/2 harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the VVT Exhaust Solenoid 1/2 on and off several times.

    Does the VVT Exhaust Solenoid 1/2 move freely without binding or sticking during actuation?

    Yes

    - Go To 11

    No

    - Replace the VVT Exhaust Solenoid 1/2 in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **VERIFY THAT THE VVT EXHAUST SOLENOID 1/2 IS ABLE TO MOVE THE PHASER**
    1. Exchange the VVT Exhaust Solenoid 1/2 with the VVT Exhaust Solenoid 2/2.

NOTE: **The Intake and Exhaust Solenoids should not be interchanged.**

2. Reconnect the solenoid harness connectors.
3. Turn the ignition on.
4. With the scan tool, erase DTCs in the PCM.
5. Test drive the vehicle under the conditions in which the fault was set.
6. With the scan tool, read DTCs.

   Did the DTC move with the solenoid or stay with the original Camshaft?

   Moved with the solenoid

   - Replace the VVT Exhaust Solenoid 1/2 in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. .
   - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   Stayed with the original camshaft

   - Go To 12

12. **CHECK THE EXHAUST CAMSHAFT 1/2 TONE WHEEL**
    1. Turn the ignition off.
    2. Remove the Cylinder Head Cover and check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

       Is the CMP Sensor Tone Wheel aligned correctly?

       Yes

       - Replace the Cam 1/2 Phaser in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
       - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Replace the Exhaust Camshaft Assembly in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** .
       - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.

3. Disconnect all related in-line harness connections (if equipped).
4. Disconnect the related component harness connectors.
5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
   - Proper connector installation.
   - Damaged connector locks.
   - Corrosion.
   - Other signs of water intrusion.
   - Weather seal damage (if equipped).
   - Bent terminals.
   - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
   - Terminals that have been pushed back into the connector cavity.
   - Check for spread terminals and verify proper terminal tension.

   Repair any conditions that are found.
6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P000C-BANK 2 CAMSHAFT 1 POSITION SLOW RESPONSE

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Variable Valve Timing (VVT) system continuously varies the Camshaft target position based on the engine operating parameters. Based on these parameters, the Powertrain Control Module (PCM) calculates or models the optimum Camshaft position. The Camshaft angular position is varied by the oil control valve. The VVT solenoid pushes on a plunger (spring loaded spool valve) in the center of the Oil Control Valve (OCV) which directs oil pressure to the hydraulic actuator (Phaser) on the Camshaft Sprocket to change the Camshaft position relative to the Crankshaft position. The VVT Solenoid, acting on the Oil Control Valve and Phaser, is controlled by the PCM. The Camshaft Position (CMP) Sensor is used to monitor the position of the Camshaft.

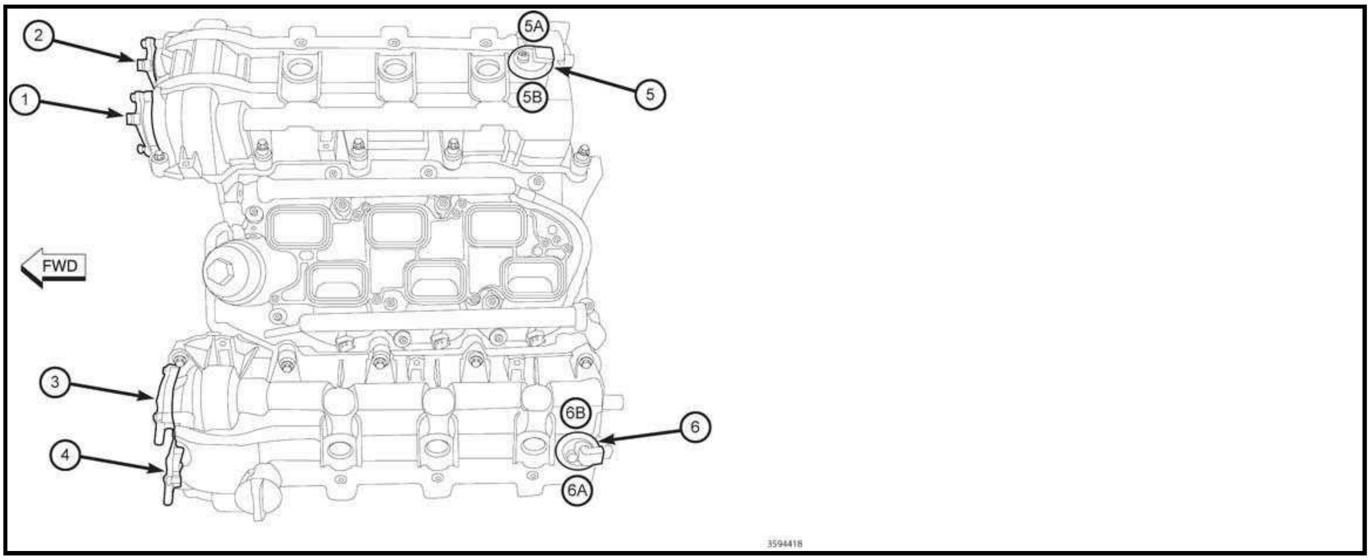
NOTE:	**For the PCM to run this diagnostic the CMP Sensor and CKP Sensor signals must be locked with no sensor faults present. A missing or erratic CMP or CKP signal cannot cause a slow response fault to set. Replacing either sensor will not fix the vehicle.**

The PCM performs the typical diagnostic checks on the control circuits. During operation of the system the PCM also performs a **Target Error** and a **Slow Response** diagnostic check of the Camshaft phasing since these conditions could potentially increase tailpipe emissions. The diagnostic is primarily performed by comparing the actual Camshaft position to that of a calculated model for the Camshaft position. This diagnostic is continuous once the enable conditions are met. The Slow Response and Target Error conditions are not performed simultaneously.

- **The Target Error** diagnostic evaluates the actual Camshaft position versus the modeled position when the Camshaft is in a relatively stable position. The difference between the two is considered to be the amount of "error". If the error amount is greater than a calibrated threshold, it is considered failing.
- **The Slow Response** diagnostic is only performed when the modeled Camshaft position is moving (phasing) in a particular direction, advancing or retarding. The modeled Camshaft phasing position is created to match only the worst possible case of a passing Camshaft position. If the actual Camshaft phasing operates slower than the model by a calibrated threshold, it is considered failing.

If either of these diagnostics fail, the Camshaft Position Slow Response fault will set. **Any oil pressure issues, VVT Solenoid or Oil Pump Solenoid Control circuit faults should be diagnosed before diagnosing a Camshaft Position Slow Response fault.**

NOTE:	**On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft Position Slow Response that is no longer present.**



NOTE:	**There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT				
CAMSHAFT POSITION	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERF DTCS**
(1) Bank 1 Intake Camshaft	P0365, P0369	P000A, P0010	P0017	P052A, P052B
(2) Bank 1 Exhaust Camshaft	P0340, P0344	P000B, P0013	P0016	P054A, P054B
(3) Bank 2 Intake Camshaft	P0390, P0394	P000C, P0020	P0019	P052C, P052D
(4) Bank 2 Exhaust Camshaft	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Engine speed is at least 650 to 1400 rpm, depending on oil temperature.
- Oil temperature is between -7B°C to 139B°C (19B°F to 282B°F).
- Battery voltage is above 10.0 volts.
- No CMP Sensor, Crankshaft Position (CKP) Sensor, or OBDI plausibility errors.
- Cam phasing is being commanded.

SET CONDITION

- The actual Camshaft position does not match the desired Camshaft position during Camshaft phasing for approximately 30.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.
- The PCM will attempt to return the Camshaft Phaser to lock pin when the fault is active.

POSSIBLE CAUSES

Possible Causes
ENGINE OIL LEVEL LOW
CAM/CRANK LEARNED VALUES OUT OF TOLERANCE
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
VVT EXHAUST SOLENOID 2/1 FAULTY OR INTERMITTENTLY BINDING/STICKING
CAMSHAFT 2/1 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT TONE WHEEL MISALIGNED
CAMSHAFT 2/1 PHASER FAULTY OR INTERMITTENTLY BINDING/STICKING
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to **PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .**

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **CHECK FOR OTHER DTCS**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and Freeze Frame Data and record on the repair order.

       Are there any system voltage, Oil Pump or Camshaft Position DTCs present?

       Yes

       - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 3
3. **VERIFY THE CAM/CRANK LEARNED VALUES ARE WITHIN TOLERANCE**
    1. With the scan tool, read the Cam/Crank Difference Learned values in the Data Display.

       NOTE: When the Cam/Crank Learn is performed the Camshaft position is learned in High Lift and Low Lift modes on the Variable Valve Lift (VVL) equipped engines. The difference between the High Lift and Low Lift learned values should be less than 2B° for each Camshaft.

       NOTE: If the Cam/Crank Difference Learned values are not in the Data Display, go to 4.

       Are the Intake Cam 2 High Lift and Low Lift learned values within 2B° of each other?

       Yes

       - Go To 4

       No

       - With the scan tool perform the **Cam/Crank Relearn** procedure and retest for DTC.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
4. **CHECK THE ENGINE OIL/ENGINE MECHANICAL CONDITION**
    1. Turn the ignition off.
    2. The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.
        - LOW ENGINE OIL LEVEL

- CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL
- INCORRECT ENGINE OIL VISCOSITY
- ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION
- ENGINE OIL PRESSURE OUT OF SPECIFICATION
- INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)

Were any of the above conditions present?

Yes

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.) in accordance with the Service Information.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

Is the oil pressure reading stable and above 16.0 psi?

Yes

- Go To 6

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE ENGINE OIL PRESSURE TO THE CYLINDER HEAD**
   1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
   2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid and install an oil pressure gauge to the adaptor.

3. Start the engine and allow it to idle.
4. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 7

No

- Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **VERIFY AN ACTIVE CONDITION BY CHECKING THE CAM PHASER POSITION**

NOTE: **If a Cam Phaser or Oil Control Valve is stuck, there may also be a Crankshaft/Camshaft Timing Misalignment and/or Multiple Cylinder Misfire DTC present.**

NOTE: **The Intake Camshaft is phased less frequently than the Exhaust Camshaft during engine operation. Therefore it may be necessary to test drive the vehicle under different load conditions to get enough phasing of the Intake Camshaft to duplicate the condition and check the values.**

1. What to monitor for during the test step:
   - **The phaser not coming back to lock pin at idle.** This his could indicate a faulty phaser or oil control valve that is permanently stuck off lock pin or a VVT Solenoid that is electrically stuck on.
   - **The actual position lagging or moving slowly toward the desired position.** This could indicate a faulty phaser or tarnished oil control valve that is dragging.
   - **The actual position lagging and then overshooting the desired position** This could indicate a faulty phaser, oil control valve or VVT Solenoid that is intermittently sticking or binding and then overshoot when the condition goes away.
2. Start the engine and allow the engine to idle.
3. With the scan tool, monitor and compare the Intake Cam 2 **actual** position value with the Intake Cam 2 **desired** position value. After comparing the two values at idle, check and compare the values at several different engine speeds during the following steps.
4. While monitoring the Intake Cam 2 actual position and desired position values:
   - Raise the engine speed quickly and hold steady for up to 30 seconds.
   - Lower the engine speed and hold steady at a level above idle (off of lock pin) for up to 30 seconds.
5. Repeat the above steps multiple times and allow the engine to come back to idle while monitoring the actual position value to verify that the phaser is returning to lock pin position.

Is the difference between the actual value and the desired value readings more than 6.0 degrees at idle or is the actual value lagging behind or overshooting the desired value?

Yes, the difference is greater than 6.0 degrees at idle:

- Go To 8

Yes, the actual reading is lagging or overshooting when changing the engine speeds indicating a binding or sticking:

- Go To 9

No

- This fault is occurring due to an intermittent condition. The problem could be due to an intermittent sticking or dragging condition of one of the timing components listed in the possible causes table. The issue could be temperature related (I.E. Incorrect or broken down oil affecting operation during a cold start, or a tolerance issue in a component that is affected after a cold start/heat soak or after the engine is warmed to operating temperature). The issue could also be occurring during certain specific driving conditions. It may be necessary to test drive the vehicle under different load conditions to duplicate the issue.

8. **DETERMINE IF THE CAM PHASER ISSUE IS ELECTRICAL OR MECHANICAL**
   1. While the engine is at idle, disconnect the VVT Intake Solenoid 2/1 harness connector.
   2. The Intake Cam 2 actual position value should change to lock pin with the solenoid disconnected. The Intake Cam position should be at approximately 146.0 degrees at lock pin.

   Did the Intake Cam 2 actual value change to lock pin position with the solenoid unplugged?

   Yes

   - Check the (K78) VVT Intake Control 2/1 circuit for a short to voltage. If the circuit is not shorted to voltage, Go To 13
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK THE CAMSHAFT 2/1 OIL CONTROL VALVE OPERATION**
   1. Turn the ignition off.
   2. Remove the VVT Intake Solenoid 2/1.
   3. Inspect the spring loaded spool valve on the Oil Control Valve.

   NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

   4. Push and release the spring loaded spool valve against the return spring with a small punch.

   NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

   Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

   Yes

   - Go To 10

No

- Replace the Camshaft 2/1 Oil Control Valve in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
- The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK THE VVT INTAKE SOLENOID 2/1 OPERATION**
    1. Turn the ignition off.
    2. With the solenoid still removed, reconnect the VVT Intake Solenoid 2/1 harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the VVT Intake Solenoid 2/1 on and off several times.

    Does the VVT Intake Solenoid 2/1 move freely without binding or sticking during actuation?

    Yes

    - Go To 11

    No

    - Replace the VVT Intake Solenoid 2/1 in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
11. **VERIFY THAT THE VVT INTAKE SOLENOID 2/1 IS ABLE TO MOVE THE PHASER**
    1. Exchange the VVT Intake Solenoid 2/1 with the VVT Intake Solenoid 1/1.

    NOTE: The Intake and Exhaust Solenoids should not be interchanged.

    2. Reconnect the solenoid harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs in the PCM.
    5. Test drive the vehicle under the conditions in which the fault was set.
    6. With the scan tool, read DTCs.

    Did the DTC move with the solenoid or stay with the original Camshaft?

    Moved with the solenoid

    - Replace the VVT Intake Solenoid 2/1 in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

Stayed with the original camshaft

- Go To 12

12. **CHECK THE INTAKE CAMSHAFT 2/1 TONE WHEEL**
    1. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    2. Using the (special tool #2027901090, Check Tool, Tone Wheel Left) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Were any issues found with the CMP Sensor Tone Wheel?

    Yes

    - Replace the Intake Camshaft Assembly in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Replace the Cam 2/1 Phaser in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
13. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P000D-BANK 2 CAMSHAFT 2 POSITION SLOW RESPONSE

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Variable Valve Timing (VVT) system continuously varies the Camshaft target position based on the engine operating parameters. Based on these parameters, the Powertrain Control Module (PCM) calculates or models the optimum Camshaft position. The Camshaft angular position is varied by the oil control valve. The VVT solenoid pushes on a plunger (spring loaded spool valve) in the center of the Oil Control Valve (OCV) which directs oil pressure to the hydraulic actuator (Phaser) on the Camshaft Sprocket to change the Camshaft position relative to the Crankshaft position. The VVT Solenoid, acting on the Oil Control Valve and Phaser, is controlled by the PCM. The Camshaft Position (CMP) Sensor is used to monitor the position of the Camshaft.

NOTE: **For the PCM to run this diagnostic the CMP Sensor and CKP Sensor signals must be locked with no sensor faults present. A missing or erratic CMP or CKP signal cannot cause a slow response fault to set. Replacing either sensor will not fix the vehicle.**

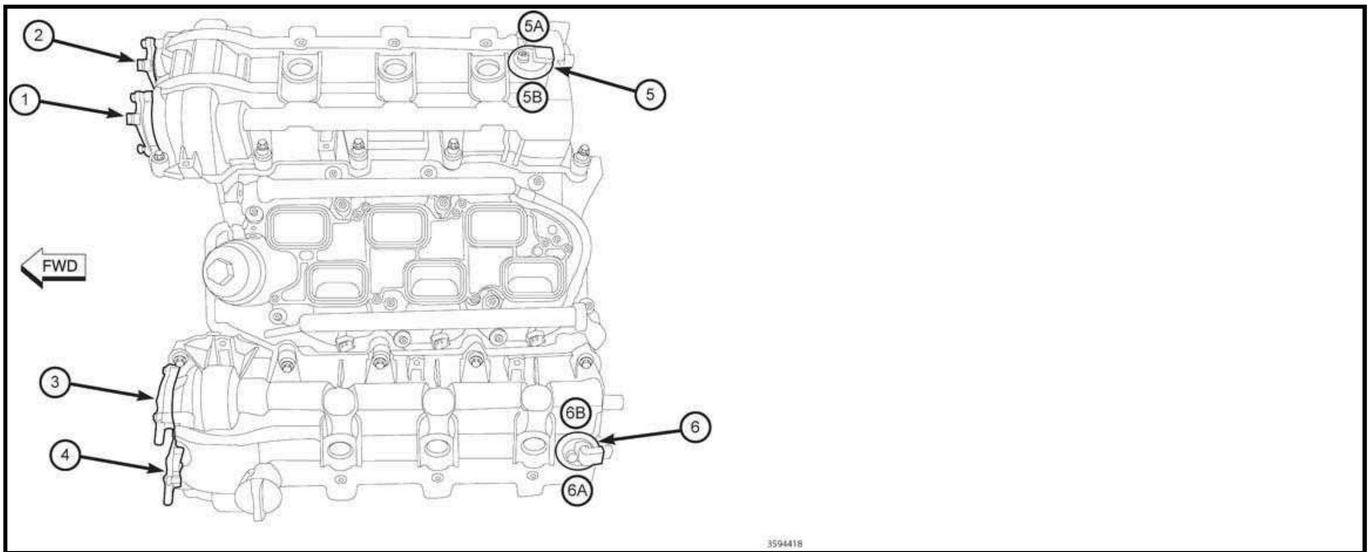
The PCM performs the typical diagnostic checks on the control circuits. During operation of the system the PCM also performs a **Target Error** and a **Slow Response** diagnostic check of the Camshaft phasing since these conditions could potentially increase tailpipe emissions. The diagnostic is primarily performed by comparing the actual Camshaft position to that of a calculated model for the Camshaft position. This diagnostic is continuous once the enable conditions are met. The Slow Response and Target Error conditions are not performed simultaneously.

- **The Target Error** diagnostic evaluates the actual Camshaft position versus the modeled position when the Camshaft is in a relatively stable position. The difference between the two is considered to be the amount of "error". If the error amount is greater than a calibrated threshold, it is considered failing.

- **The Slow Response** diagnostic is only performed when the modeled Camshaft position is moving (phasing) in a particular direction, advancing or retarding. The modeled Camshaft phasing position is created to match only the worst possible case of a passing Camshaft position. If the actual Camshaft phasing operates slower than the model by a calibrated threshold, it is considered failing.

If either of these diagnostics fail, the Camshaft Position Slow Response fault will set. **Any oil pressure issues, VVT Solenoid or Oil Pump Solenoid Control circuit faults should be diagnosed before diagnosing a Camshaft Position Slow Response fault.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft Position Slow Response that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT				
CAMSHAFT POSITION	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERF DTCS**
(1) Bank 1 Intake Camshaft	P0365, P0369	P000A, P0010	P0017	P052A, P052B
(2) Bank 1 Exhaust Camshaft	P0340, P0344	P000B, P0013	P0016	P054A, P054B
(3) Bank 2 Intake Camshaft	P0390, P0394	P000C, P0020	P0019	P052C, P052D
(4) Bank 2 Exhaust Camshaft	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Engine speed is at least 650 to 1400 rpm, depending on oil temperature.
- Oil temperature is between -7B°C to 139B°C (19B°F to 282B°F).

- Battery voltage is above 10.0 volts.
- No CMP Sensor, Crankshaft Position (CKP) Sensor, or OBDI plausibility errors.
- Cam phasing is being commanded.

SET CONDITION

- The actual Camshaft position does not match the desired Camshaft position during Camshaft phasing for approximately 30.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.
- The PCM will attempt to return the Camshaft Phaser to lock pin when the fault is active.

POSSIBLE CAUSES

Possible Causes
ENGINE OIL LEVEL LOW
CAM/CRANK LEARNED VALUES OUT OF TOLERANCE
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
VVT EXHAUST SOLENOID 2/2 FAULTY OR INTERMITTENTLY BINDING/STICKING
CAMSHAFT 2/2 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT TONE WHEEL MISALIGNED
CAMSHAFT 2/2 PHASER FAULTY OR INTERMITTENTLY BINDING/STICKING
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

       No

       - Go To 2
2. **CHECK FOR OTHER DTCS**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and Freeze Frame Data and record on the repair order.

       Are there any system voltage, Oil Pump or Camshaft Position DTCs present?

Yes

- Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

No

- Go To 3

3. **VERIFY THE CAM/CRANK LEARNED VALUES ARE WITHIN TOLERANCE**
   1. With the scan tool, read the Cam/Crank Difference Learned values in the Data Display.

NOTE:	**When the Cam/Crank Learn is performed the Camshaft position is learned in High Lift and Low Lift modes on the Variable Valve Lift (VVL) equipped engines. The difference between the High Lift and Low Lift learned values should be less than 2B° for each Camshaft.**

NOTE:	**If the Cam/Crank Difference Learned values are not in the Data Display, go to 4.**

Are the Exhaust Cam 2 High Lift and Low Lift learned values within 2B° of each other?

Yes

- Go To 4

No

- With the scan tool perform the **Cam/Crank Relearn** procedure and retest for DTC.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE ENGINE OIL/ENGINE MECHANICAL CONDITION**
   1. Turn the ignition off.

NOTE:	**The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.** • **LOW ENGINE OIL LEVEL** • **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL** • **INCORRECT ENGINE OIL VISCOSITY** • **ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION** • **ENGINE OIL PRESSURE OUT OF SPECIFICATION** • **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

Were any of the above conditions present?

Yes

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.) in accordance with the Service Information.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

   NOTE: During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.

   1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
   2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
   3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
   4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor.
   5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

      NOTE: If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.

   Is the oil pressure reading stable and above 16.0 psi?

   Yes

   - Go To 6

   No

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE ENGINE OIL PRESSURE TO THE CYLINDER HEAD**
   1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
   2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid and install an oil pressure gauge to the adaptor.
   3. Start the engine and allow it to idle.
   4. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

      NOTE: The oil pressure reading at the Cylinder Head should be above 14.0 psi.

   Is the oil pressure reading stable and above 14.0 psi?

   Yes

   - Go To 7

   No

   - Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **VERIFY AN ACTIVE CONDITION BY CHECKING THE CAM PHASER POSITION**

NOTE: **If a Cam Phaser or Oil Control Valve is stuck, there may also be a Crankshaft/Camshaft Timing Misalignment and/or Multiple Cylinder Misfire DTC present.**

1. What to monitor for during the test step:
   - **The phaser not coming back to lock pin at idle.** This his could indicate a faulty phaser or oil control valve that is permanently stuck off lock pin or a VVT Solenoid that is electrically stuck on.
   - **The actual position lagging or moving slowly toward the desired position.** This could indicate a faulty phaser or tarnished oil control valve that is dragging.
   - **The actual position lagging and then overshooting the desired position** This could indicate a faulty phaser, oil control valve or VVT Solenoid that is intermittently sticking or binding and then overshoot when the condition goes away.
2. Start the engine and allow the engine to idle.
3. With the scan tool, monitor and compare the Exhaust Cam 2 **actual** position value with the Exhaust Cam 2 **desired** position value. After comparing the two values at idle, check and compare the values at several different engine speeds during the following steps.
4. While monitoring the Exhaust Cam 2 actual position and desired position values:
   - Raise the engine speed quickly and hold steady for up to 30 seconds.
   - Lower the engine speed and hold steady at a level above idle (off of lock pin) for up to 30 seconds.
5. Repeat the above steps multiple times and allow the engine to come back to idle while monitoring the actual position value to verify that the phaser is returning to lock pin position.

   Is the difference between the actual value and the desired value readings more than 6.0 degrees at idle or is the actual value lagging behind or overshooting the desired value?

   Yes, the difference is greater than 6.0 degrees at idle:

   - Go To 8

   Yes, the actual reading is lagging or overshooting when changing the engine speeds indicating a binding or sticking:

   - Go To 9

   No

   - This fault is occurring due to an intermittent condition. The problem could be due to an intermittent sticking or dragging condition of one of the timing components listed in the possible causes table. The issue could be temperature related (I.E. Incorrect or broken down oil affecting operation during a cold start, or a tolerance issue in a component that is affected after a cold start/heat soak or after the engine is warmed to operating temperature). The issue could also be occurring during certain specific driving conditions. It may be necessary to test drive the vehicle under different load conditions to duplicate the issue.

8. **DETERMINE IF THE CAM PHASER ISSUE IS ELECTRICAL OR MECHANICAL**

1. While the engine is at idle, disconnect the VVT Exhaust Solenoid 2/2 harness connector.
2. The Exhaust Cam 2 actual position value should change to lock pin with the solenoid disconnected. The Exhaust Cam position should be at approximately 123.0 degrees at lock pin.

   Did the Exhaust Cam 2 actual value change to lock pin position with the solenoid unplugged?

   Yes

   - Check the (K277) VVT Exhaust Control 2/2 circuit for a short to voltage. If the circuit is not shorted to voltage, Go To 13
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK THE CAMSHAFT 2/2 OIL CONTROL VALVE OPERATION**
   1. Turn the ignition off.
   2. Remove the VVT Exhaust Solenoid 2/2.
   3. Inspect the spring loaded spool valve on the Oil Control Valve.

      NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

   4. Push and release the spring loaded spool valve against the return spring with a small punch.

      NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

   Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

   Yes

   - Go To 10

   No

   - Replace the Camshaft 2/2 Oil Control Valve in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
   - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK THE VVT EXHAUST SOLENOID 2/2 OPERATION**
    1. Turn the ignition off.
    2. With the solenoid still removed, reconnect the VVT Exhaust Solenoid 2/2 harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the VVT Exhaust Solenoid 2/2 on and off several times.

    Does the VVT Exhaust Solenoid 2/2 move freely without binding or sticking during actuation?

    Yes

- Go To 11

No

- Replace the VVT Exhaust Solenoid 2/2 in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
- The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **VERIFY THAT THE VVT EXHAUST SOLENOID 2/2 IS ABLE TO MOVE THE PHASER**
    1. Exchange the VVT Exhaust Solenoid 2/2 with the VVT Exhaust Solenoid 1/2.

       NOTE: The Intake and Exhaust Solenoids should not be interchanged.

    2. Reconnect the solenoid harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs in the PCM.
    5. Test drive the vehicle under the conditions in which the fault was set.
    6. With the scan tool, read DTCs.

    Did the DTC move with the solenoid or stay with the original Camshaft?

    Moved with the solenoid

    - Replace the VVT Exhaust Solenoid 2/2 in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    Stayed with the original camshaft

    - Go To 12

12. **CHECK THE EXHAUST CAMSHAFT 2/2 TONE WHEEL**
    1. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    2. Using the (special tool #2027901090, Check Tool, Tone Wheel Left) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Were any issues found with the CMP Sensor Tone Wheel?

    Yes

    - Replace the Exhaust Camshaft Assembly in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** .
    - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Replace the Cam 2/2 Phaser in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** .
- The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

P0010-BANK 1 CAMSHAFT 1 POSITION ACTUATOR CIRCUIT OPEN

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Variable Valve Timing (VVT) system continuously varies the Camshaft target position based on the engine operating parameters. Based on these parameters, the Powertrain Control Module (PCM) calculates or models the optimum Camshaft position. The Camshaft angular position is varied by the oil control valve. The VVT solenoid pushes on a plunger (spring loaded spool valve) in the center of the Oil Control Valve (OCV) which directs oil pressure to the hydraulic actuator (Phaser) on the Camshaft Sprocket to change the Camshaft position relative to the Crankshaft position. The VVT Solenoid, acting on the Oil Control Valve and Phaser, is controlled by the PCM. The Camshaft Position (CMP) Sensor is used to monitor the position of the Camshaft.

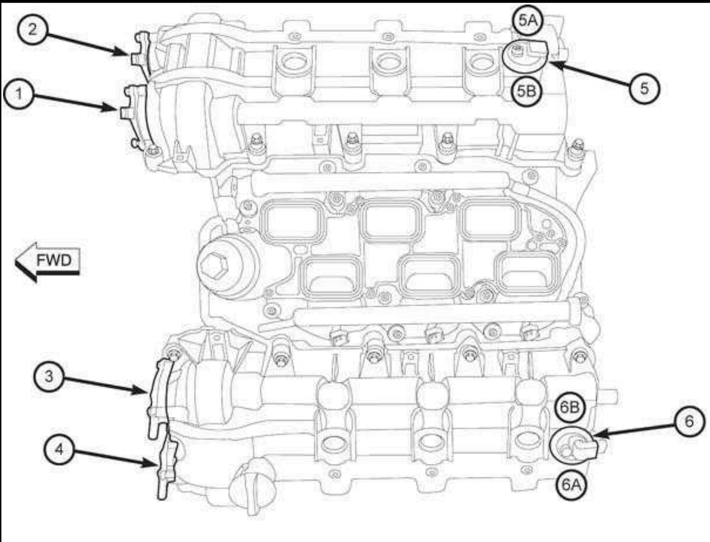
NOTE: **For the PCM to run this diagnostic the CMP Sensor and CKP Sensor signals must be locked with no sensor faults present. A missing or erratic CMP or CKP signal cannot cause a slow response fault to set. Replacing either sensor will not fix the vehicle.**

The PCM performs the typical diagnostic checks on the control circuits. During operation of the system the PCM also performs a **Target Error** and a **Slow Response** diagnostic check of the Camshaft phasing since these conditions could potentially increase tailpipe emissions. The diagnostic is primarily performed by comparing the actual Camshaft position to that of a calculated model for the Camshaft position. This diagnostic is continuous once the enable conditions are met. The Slow Response and Target Error conditions are not performed simultaneously.

- **The Target Error** diagnostic evaluates the actual Camshaft position versus the modeled position when the Camshaft is in a relatively stable position. The difference between the two is considered to be the amount of "error". If the error amount is greater than a calibrated threshold, it is considered failing.
- **The Slow Response** diagnostic is only performed when the modeled Camshaft position is moving (phasing) in a particular direction, advancing or retarding. The modeled Camshaft phasing position is created to match only the worst possible case of a passing Camshaft position. If the actual Camshaft phasing operates slower than the model by a calibrated threshold, it is considered failing.

If either of these diagnostics fail, the Camshaft Position Slow Response fault will set. **Any oil pressure issues, VVT Solenoid or Oil Pump Solenoid Control circuit faults should be diagnosed before diagnosing a Camshaft Position Slow Response fault.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft Position Slow Response that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

(4) Bank 2 Exhaust Camshaft	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage greater than 10.4 volts.

SET CONDITION

- The Powertrain Control Module (PCM) has detected a circuit failure on the VVT Intake Solenoid 1/1 control circuitry.

DEFAULT ACTION

- The MIL will illuminate.
- The stop/start system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
VVT INTAKE SOLENOID 1/1 CONTROL CIRCUIT SHORTED TO GROUND

Possible Causes
VVT INTAKE SOLENOID 1/1 CONTROL CIRCUIT SHORTED TO VOLTAGE
VVT INTAKE SOLENOID 1/1 CONTROL CIRCUIT OPEN/HIGH RESISTANCE
VVT INTAKE SOLENOID 1/1 GROUND CIRCUIT OPEN/HIGH RESISTANCE
VVT INTAKE SOLENOID 1/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK THE VVT INTAKE SOLENOID 1/1 CONNECTOR AND TERMINALS**
    1. Turn the ignition off.
    2. Check the VVT Intake Solenoid 1/1 harness connector for proper connection at the VVT Intake Solenoid 1/1.
    3. Verify that the connector is completely plugged in and properly locked prior to disconnecting.

4. Disconnect the VVT Intake Solenoid 1/1 harness connector and check for any pushed out, damaged or spread terminals.

   Were any issues found with the connector or terminals?

   Yes

   - Repair the damaged terminal or properly connect and lock the VVT Intake Solenoid 1/1 harness connector and retest for DTCs.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 4

4. **ISOLATE AND CHECK THE VVT INTAKE SOLENOID 1/1 (K76) CONTROL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

      NOTE: **There should be no continuity between ground and the circuit being tested.**

      Is there continuity between ground and the circuit being tested?

      Yes

      - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 5

5. **ISOLATE AND CHECK THE VVT INTAKE SOLENOID 1/1 (K76) CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.

4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

   Is there continuity between the circuit being tested and any other circuit?

   Yes

   - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 6

6. **CHECK THE (Z904) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
   1. Disconnect the component harness connector to isolate the ground circuit.
   2. Connect the positive lead of the load test tool to the positive side of the Battery.
   3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
   4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

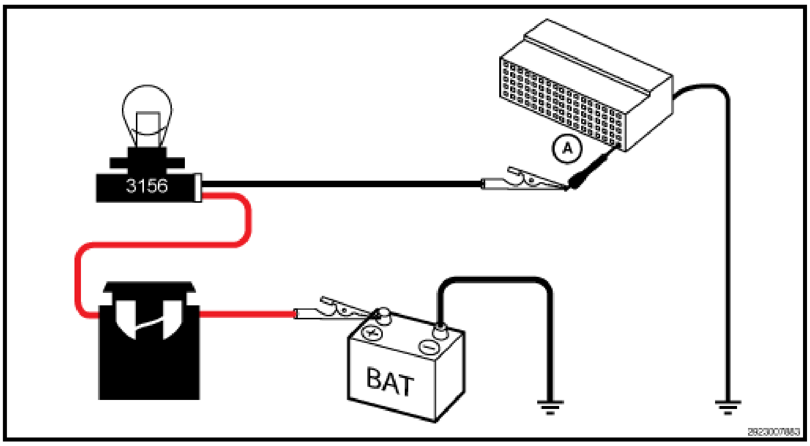
NOTE: **Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
- **3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 7

   No

   - Repair the ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **ISOLATE AND LOAD TEST THE VVT INTAKE SOLENOID 1/1 (K76) CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
    1. The ignition must be off when performing a load test on a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
    3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
    4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
    5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
    6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

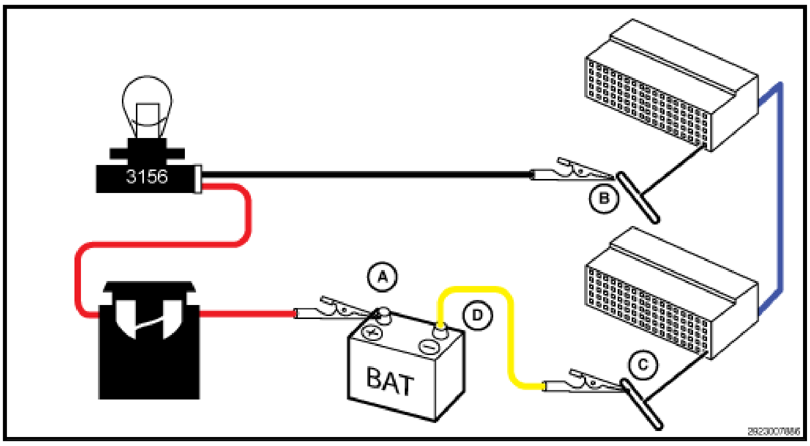
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
- **3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: **To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.**

CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 8

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **ACTUATE AND CHECK THE OPERATION OF THE VVT INTAKE SOLENOID 1/1 DRIVER**
   1. Reconnect the PCM C2 harness connector.
   2. Turn the ignition on.
   3. Using a 12-volt test light connected to ground, probe the VVT Intake Solenoid 1/1 (K76) Control circuit in the VVT Intake Solenoid 1/1 harness connector.

NOTE: The PCM will command the solenoid ON briefly after the ignition is turned on. This is a normal condition. The test light will illuminate briefly and then turn off and stay off if there is not a short to voltage.

4. With the scan tool, actuate the VVT Intake Solenoid 1/1 Control to the highest duty cycle (80%) position.

   NOTE: The test light should be illuminated and bright. Compare the brightness to that of a direct connection to the Battery.

   Is the test light illuminated and bright?

   Yes

   - Replace the VVT Intake Solenoid 1/1 in accordance with the Service Information. With the scan tool perform the **Cam/Crank Relearn** procedure. Refer to **SOLENOID, REMOVAL AND INSTALLATION** .
   - The **Cam/Crank Relearn** procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.
   6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   9. With the scan tool, erase DTCs.

10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0013-BANK 1 CAMSHAFT 2 POSITION ACTUATOR CIRCUIT OPEN

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Variable Valve Timing (VVT) system continuously varies the Camshaft target position based on the engine operating parameters. Based on these parameters, the Powertrain Control Module (PCM) calculates or models the optimum Camshaft position. The Camshaft angular position is varied by the oil control valve. The VVT solenoid pushes on a plunger (spring loaded spool valve) in the center of the Oil Control Valve (OCV) which directs oil pressure to the hydraulic actuator (Phaser) on the Camshaft Sprocket to change the Camshaft position relative to the Crankshaft position. The VVT Solenoid, acting on the Oil Control Valve and Phaser, is controlled by the PCM. The Camshaft Position (CMP) Sensor is used to monitor the position of the Camshaft.

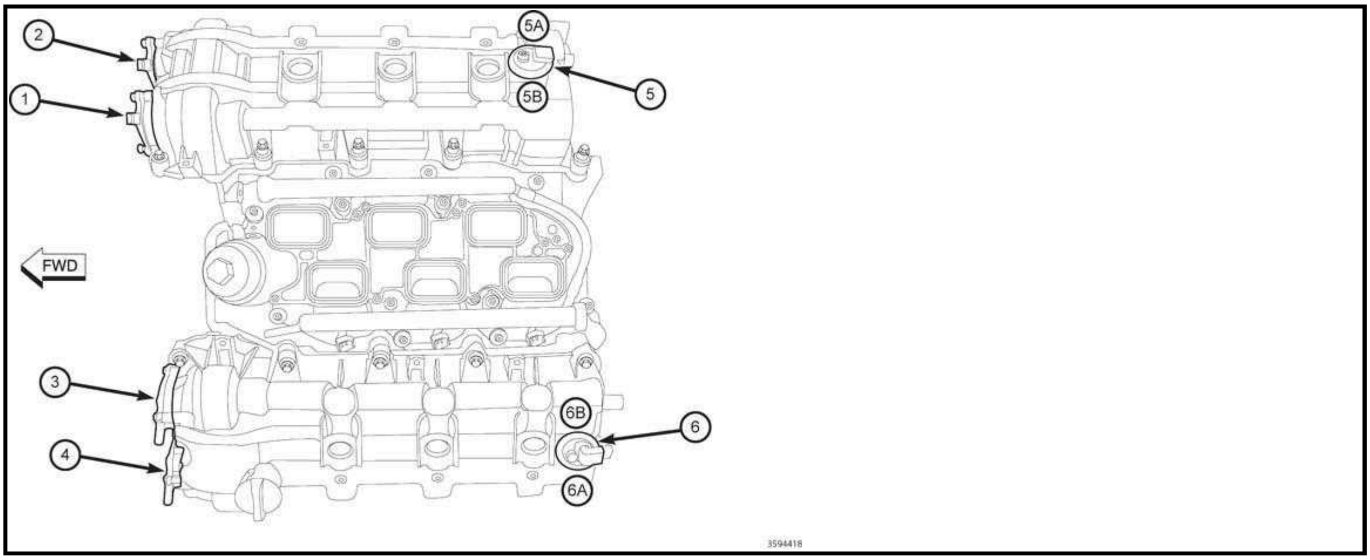
NOTE: **For the PCM to run this diagnostic the CMP Sensor and CKP Sensor signals must be locked with no sensor faults present. A missing or erratic CMP or CKP signal cannot cause a slow response fault to set. Replacing either sensor will not fix the vehicle.**

The PCM performs the typical diagnostic checks on the control circuits. During operation of the system the PCM also performs a **Target Error** and a **Slow Response** diagnostic check of the Camshaft phasing since these conditions could potentially increase tailpipe emissions. The diagnostic is primarily performed by comparing the actual Camshaft position to that of a calculated model for the Camshaft position. This diagnostic is continuous once the enable conditions are met. The Slow Response and Target Error conditions are not performed simultaneously.

- **The Target Error** diagnostic evaluates the actual Camshaft position versus the modeled position when the Camshaft is in a relatively stable position. The difference between the two is considered to be the amount of "error". If the error amount is greater than a calibrated threshold, it is considered failing.
- **The Slow Response** diagnostic is only performed when the modeled Camshaft position is moving (phasing) in a particular direction, advancing or retarding. The modeled Camshaft phasing position is created to match only the worst possible case of a passing Camshaft position. If the actual Camshaft phasing operates slower than the model by a calibrated threshold, it is considered failing.

If either of these diagnostics fail, the Camshaft Position Slow Response fault will set. **Any oil pressure issues, VVT Solenoid or Oil Pump Solenoid Control circuit faults should be diagnosed before diagnosing a Camshaft Position Slow Response fault.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft Position Slow Response that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT				
CAMSHAFT POSITION	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERF DTCS**
(1) Bank 1 Intake Camshaft	P0365, P0369	P000A, P0010	P0017	P052A, P052B
(2) Bank 1 Exhaust Camshaft	P0340, P0344	P000B, P0013	P0016	P054A, P054B
(3) Bank 2 Intake Camshaft	P0390, P0394	P000C, P0020	P0019	P052C, P052D
(4) Bank 2 Exhaust Camshaft	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage greater than 10.4 volts.

SET CONDITION

- The PCM detects an open or shorted condition on the VVT Exhaust Solenoid 1/2 Control circuitry.

DEFAULT ACTION

- The MIL will illuminate.
- The stop/start system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
VVT EXHAUST SOLENOID 1/2 CONTROL CIRCUIT SHORTED TO GROUND
VVT EXHAUST SOLENOID 1/2 CONTROL CIRCUIT SHORTED TO VOLTAGE
VVT EXHAUST SOLENOID 1/2 CONTROL CIRCUIT OPEN/HIGH RESISTANCE
VVT EXHAUST SOLENOID 1/2 GROUND CIRCUIT OPEN/HIGH RESISTANCE
VVT EXHAUST SOLENOID 1/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK THE VVT EXHAUST SOLENOID 1/2 CONNECTOR AND TERMINALS**
    1. Turn the ignition off.

2. Check the VVT Exhaust Solenoid 1/2 harness connector for proper connection at the VVT Exhaust Solenoid 1/2.
3. Verify that the connector is completely plugged in and properly locked prior to disconnecting.
4. Disconnect the VVT Exhaust Solenoid 1/2 harness connector and check for any pushed out, damaged or spread terminals.

Were any issues found with the connector or terminals?

Yes

- Repair the damaged terminal or properly connect and lock the VVT Exhaust Solenoid 1/2 harness connector and retest for DTCs.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 4

4. **ISOLATE AND CHECK THE VVT EXHAUST SOLENOID 1/2 (K276) CONTROL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **ISOLATE AND CHECK THE VVT EXHAUST SOLENOID 1/2 (K276) CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
   4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to**

pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK THE (Z904) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
    1. Disconnect the component harness connector to isolate the ground circuit.
    2. Connect the positive lead of the load test tool to the positive side of the Battery.
    3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
    4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

NOTE: **Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

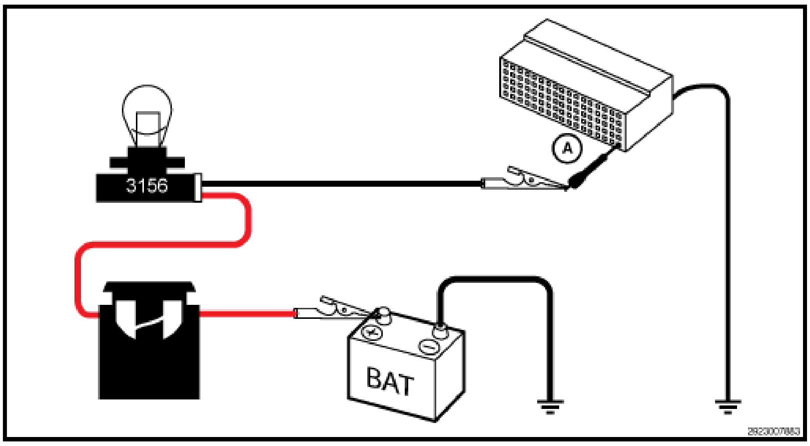
NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**

3. 3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 7

   No

   - Repair the ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

7. **ISOLATE AND LOAD TEST THE VVT EXHAUST SOLENOID 1/2 (K276) CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
   1. The ignition must be off when performing a load test on a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.

3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

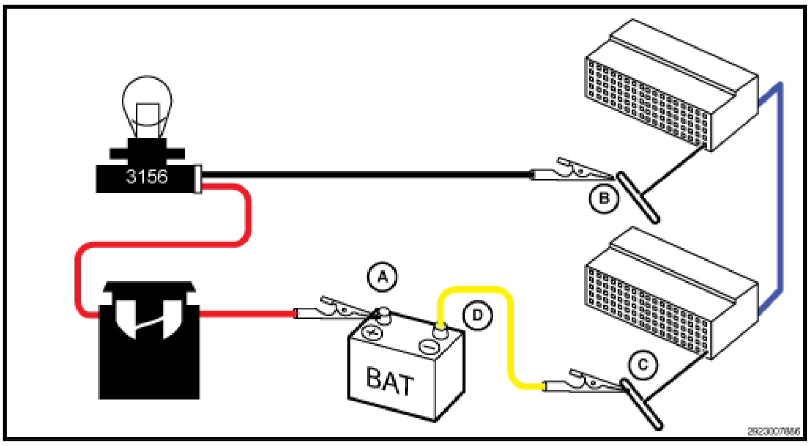
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 8

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **ACTUATE AND CHECK THE OPERATION OF THE VVT EXHAUST SOLENOID 1/2 DRIVER**
   1. Reconnect the PCM C2 harness connector.
   2. Turn the ignition on.
   3. Using a 12-volt test light connected to ground, probe the VVT Exhaust Solenoid 1/2 (K276) Control circuit in the VVT Exhaust Solenoid 1/2 harness connector.

   NOTE: **The PCM will command the solenoid ON briefly after the ignition is turned on. This is a normal condition. The test light will illuminate briefly and then turn off and stay off if there is not a short to voltage.**

   4. With the scan tool, actuate the VVT Exhaust Solenoid 1/2 Control to the highest duty cycle (80%) position.

   NOTE: **The test light should be illuminated and bright. Compare the brightness to that of a direct connection to the Battery.**

Is the test light illuminated and bright?

Yes

- Replace the VVT Exhaust Solenoid 1/2 in accordance with the Service Information. Refer to **SOLENOID, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0016-CRANKSHAFT/CAMSHAFT TIMING MISALIGNMENT - BANK 1 SENSOR 1

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

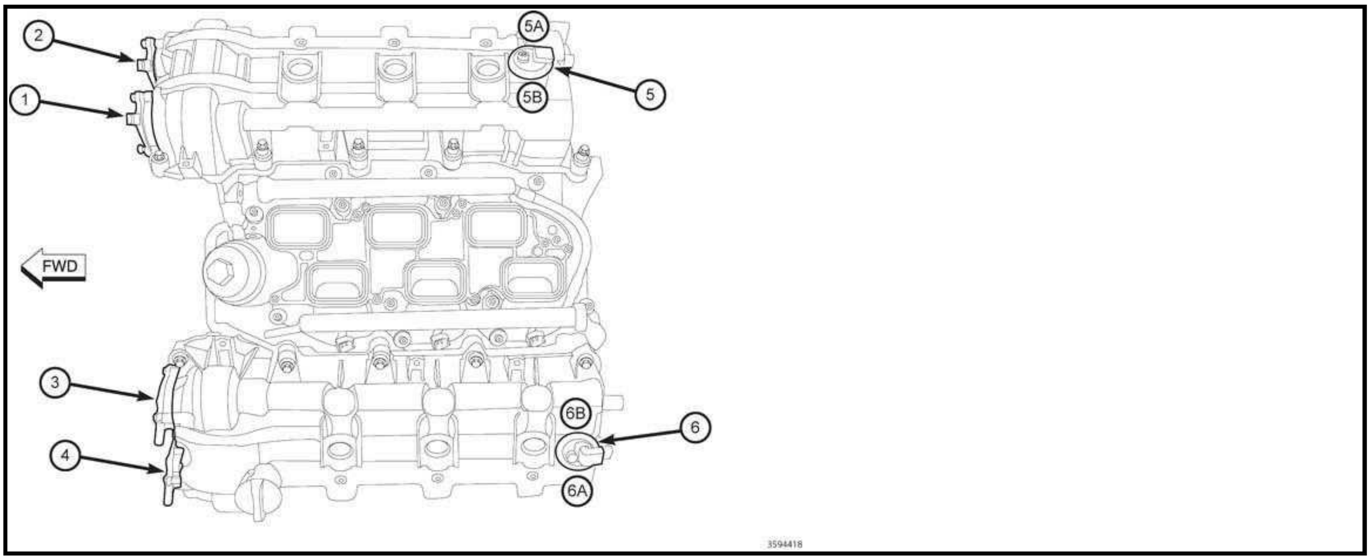
For proper engine control and combustion stability the Camshaft (CMP) and Crankshaft (CKP) positions must be aligned and known so that fuel injection and spark timing can be introduced at the intended Piston and Intake/Exhaust Valve positions. During vehicle manufacturing, at end of line, or if a Cam/Crank Relearn is performed, the system learns the difference between the Camshaft and Crankshaft position in terms of engine degrees and stores it in the EEPROM. During every following driving cycle, the Powertrain Control Module (PCM) uses this value to compare.

Within a driving cycle, once the CMP position and CKP position are known and verified they are considered "locked." This diagnostic will only run when both sensor signals are in the "locked" state. Engine position is constantly tracked as the CMP Sensor and CKP Sensor signals are monitored by the PCM. An engine rotating at a constant speed would produce engine signals that match the nominal pattern exactly. With engine acceleration and deceleration the engine signals are compressed or stretched in time relative to nominal timing. The PCM takes into account and adjusts for any acceleration/deceleration rates that are in effect.

The misalignment fault accounts for angular deviation between the CMP Sensor and CKP Sensor signals due to miss builds, chain stretch, or skipped tooth. This fault results from the difference between the positions as indicated by the CMP Sensor and CKP Sensor signals. The result is only valid if both positions are "locked".

NOTE: **A missing or erratic CMP or CKP signal cannot cause a Cam/Crank Misalignment fault to set. Replacing either sensor will not fix the vehicle.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft/Crankshaft Misalignment that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	**CALLOUT #**	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERF DTCS**
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Battery voltage above 11.0 volts.
- Engine speed between approximately 500 - 6000 rpm, depending on PCM calibration.
- Engine coolant temperature above 10B°C (50B°F).
- Engine oil temperature is above between 5B°C (41B°F) and 10B°C (50B°F), depending on PCM calibration.
- Camshaft has been driven to lock pin for approximately 3 - 4 seconds or more (to allow enough time to attain lock pin position).

SET CONDITION

- The difference between the Bank 1 Exhaust Camshaft position and the Crankshaft position is more than 10.0 degrees.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INCORRECT ENGINE OIL VISCOSITY OR OIL FILTER
CAM/CRANK LEARNED VALUES OUT OF TOLERANCE
ENGINE OIL AERATED OR CONTAMINATED
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
CAMSHAFT 1/2 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT TONE WHEEL MISALIGNED
CAMSHAFT 1/2 PHASER
TIMING CHAIN/SPROCKET ALIGNMENT
BROKEN OR FAULTY TIMING CHAIN TENSIONER OR GUIDES
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE DTC**

   NOTE: **Perform any Service Bulletins or Star Cases relating to this fault before continuing with this test procedure.**

   1. Turn the ignition on.
   2. With the scan tool, read DTCs and record on the repair order.
   3. Record the related Freeze Frame data.
   4. With the scan tool, erase DTCs.
   5. Start the engine and allow it to idle. It maybe necessary to tests drive the vehicle and allow cam phasing to occur in order to reset the fault.

      WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

   6. With the scan tool, read DTCs.

      Is the DTC active or pending?

      Yes

      - Go To 2

      No

      - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are the P0340 or P0344 DTCs present?

      Yes

      - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

      No

      - Go To 3
3. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are there any VVT Solenoid Circuit Open or Slow Response DTCs active or pending?

      Yes

      - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

      No

      - Go To 4
4. **VERIFY THE CAM/CRANK LEARNED VALUES ARE WITHIN TOLERANCE**

1. With the scan tool, read the Cam/Crank Difference Learned values in the Data Display.

   NOTE: **When the Cam/Crank Learn is performed the Camshaft position is learned in High Lift and Low Lift modes on the Variable Valve Lift (VVL) equipped engines. The difference between the High Lift and Low Lift learned values should be less than 2B° for each Camshaft.**

   NOTE: **If the Cam/Crank Difference Learned values are not in the Data Display, go to 5.**

   Are the Exhaust Cam 1 High Lift and Low Lift learned values within 2B° of each other?

   Yes

   - Go To 5

   No

   - With the scan tool perform the **Cam/Crank Relearn** procedure and retest for DTC.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **ENGINE OIL/ENGINE MECHANICAL**

   NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

   - **ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION**
   - **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
   - **LOW ENGINE OIL LEVEL**
   - **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**
   - **DETERIORATED OR DIRTY OIL**
   - **CONTAMINATED ENGINE OIL**
   - **INCORRECT ENGINE OIL VISCOSITY**
   - **AERATED ENGINE OIL**

   1. If any of the above conditions are found, repair as necessary.

      Were any of the above conditions present?

      Yes

      - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 6

6. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**
   1. Install the applicable adaptor to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
   2. Start the engine and allow it to idle.

3. Monitor the engine oil pressure reading on the gauge or scan tool.

NOTE: **If the oil pressure is below 14 psi or oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or Cam/Crank Misalignment DTC.**

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 7

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **VERIFY AN ACTIVE CONDITION BY CHECKING THE CAM PHASER POSITION**

NOTE: **If a Cam Phaser or Oil Control Valve is stuck, there may also be a Crankshaft/Camshaft Timing Misalignment and/or Multiple Cylinder Misfire DTC present.**

NOTE: **It may be necessary to drive the vehicle to allow the Cam Phaser to operate normally and then return to lock pin at idle. The purpose is to check for a phaser that may not be responding quick enough and causing this DTC.**

NOTE: **The Cam Phaser slow response fault can take approximately 30 seconds to fail, where as the misalignment fault generally fails within 5-10 seconds.**

1. What to monitor for during the test step:
   - **The phaser not coming back to lock pin at idle.** This his could indicate a faulty phaser or oil control valve that is permanently stuck off lock pin or a Camshaft Position Solenoid that is electrically stuck on.
   - **The actual position lagging or moving slowly toward the desired position.** This could indicate a faulty phaser or tarnished oil control valve that is dragging.
   - **The actual position lagging and then overshooting the desired position** This could indicate a faulty phaser, oil control valve or Camshaft Position Solenoid that is intermittently sticking or binding and then overshoot when the condition goes away.
2. Start the engine and allow the engine to idle.
3. With the scan tool, monitor and compare the Exhaust Cam 1 **actual** position value with the Exhaust Cam 1 **desired** position value. After comparing the two values at idle, check and compare the values at several different engine speeds during the following steps.
4. While monitoring the Exhaust Cam 1 actual position and desired position values:
   - Raise the engine speed quickly and hold steady for up to 30 seconds.
   - Lower the engine speed and hold steady at a level above idle (off of lock pin) for up to 30 seconds.
5. Repeat the above steps multiple times and allow the engine to come back to idle while monitoring the actual position value to verify that the phaser is returning to lock pin position.

   Is the difference between the actual value and the desired value readings more than 10.0 degrees at idle or is the actual value lagging behind or overshooting the desired value?

Yes, the difference is greater than 10.0 degrees at idle:

- Go To 8

Yes, the actual reading is lagging or overshooting when changing the engine speeds indicating a binding or sticking condition:

- Go To 9

No

- Go To 12

8. **DETERMINE IF THE CAM PHASER ISSUE IS ELECTRICAL OR MECHANICAL**
    1. While the engine is at idle, disconnect the Camshaft 1/2 Position Solenoid harness connector.
    2. The Exhaust Cam 1 actual position value should change to lock pin with the solenoid disconnected. The Exhaust Cam position should be at approximately 123.0 degrees at lock pin.

    Did the Exhaust Cam 1 actual value change to lock pin position with the solenoid unplugged?

    Yes

    - Check the (K276) VVT Exhaust Control 1/2 circuit for a short to voltage. If the circuit is not shorted to voltage, replace the Powertrain Control Module in accordance with the service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 9
9. **CHECK THE CAMSHAFT 1/2 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.
    2. Remove the Camshaft 1/2 Position Solenoid.
    3. Inspect the spring loaded spool valve on the Oil Control Valve.

    NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

    4. Push and release the spring loaded spool valve against the return spring with a small punch.

    NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

    Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

    Yes

    - Go To 10

    No

    - Replace the Camshaft 1/2 Oil Control Valve in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing

chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK THE CAMSHAFT 1/2 POSITION SOLENOID OPERATION**
    1. Turn the ignition off.
    2. With the solenoid still removed, reconnect the Camshaft 1/2 Position Solenoid harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the Camshaft 1/2 Position Solenoid on and off several times.

    Does the Camshaft 1/2 Position Solenoid move freely without binding or sticking during actuation?

    Yes

    - Go To 11

    No

    - Replace the Camshaft 1/2 Position Solenoid in accordance with the Service Information.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **VERIFY THAT THE CAMSHAFT 1/2 POSITION SOLENOID IS ABLE TO MOVE THE PHASER**
    1. Exchange the Camshaft 1/2 Position Solenoid with the Camshaft 2/2 Position Solenoid.

    NOTE: The Intake and Exhaust Solenoids should not be interchanged.

    2. Reconnect the solenoid harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs in the PCM.
    5. Test drive the vehicle under the conditions in which the fault was set.
    6. With the scan tool, read DTCs.

    Did the DTC move with the solenoid or stay with the original Camshaft?

    Moved with the solenoid:

    - Replace the faulty Camshaft 1/2 Position Solenoid in accordance with the Service Information.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    Stayed with the original camshaft:

    - Go To 12

12. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Turn the ignition off.
    2. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    3. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Is the CMP Sensor Tone Wheel aligned correctly?

Yes

- Go To 13

No

- Replace the Exhaust Camshaft Assembly in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE TIMING ALIGNMENT**
    1. Verify proper alignment of the Timing Chain and gears in accordance with the Service Information. Also check the Timing Chain Tensioner and Guide for faulty or broken components.

       Were any issue found with the timing alignment or components?

       Yes

       - Perform the appropriate repair in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Replace the Cam Phaser Assembly in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0017-CRANKSHAFT/CAMSHAFT TIMING MISALIGNMENT - BANK 1 SENSOR 2

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

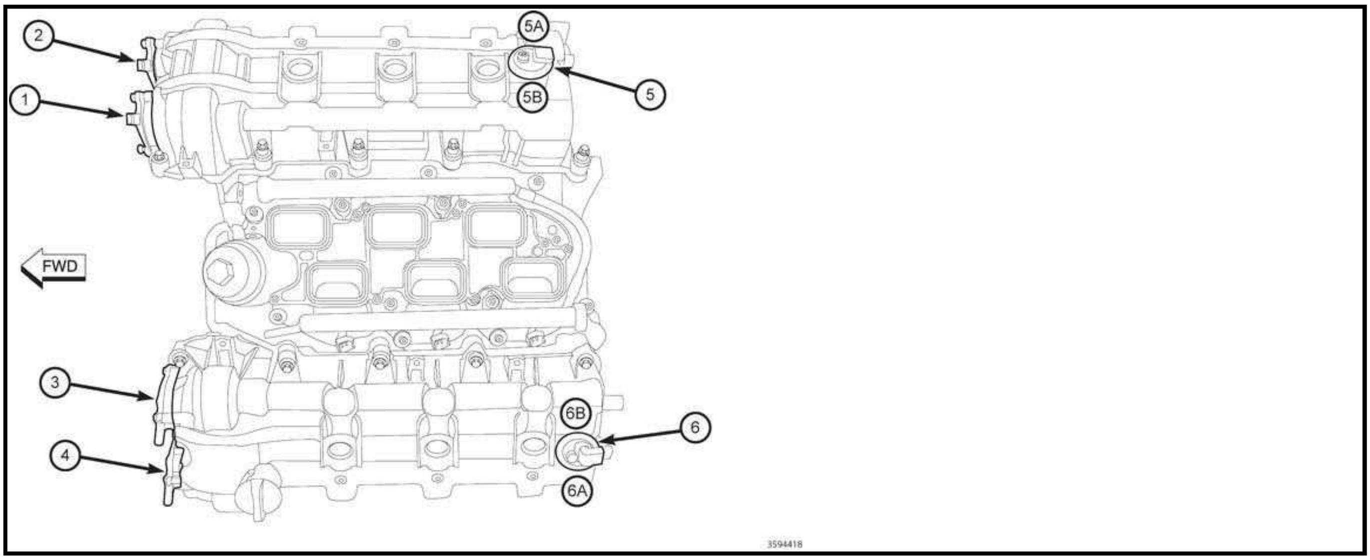
For proper engine control and combustion stability the Camshaft (CMP) and Crankshaft (CKP) positions must be aligned and known so that fuel injection and spark timing can be introduced at the intended Piston and Intake/Exhaust Valve positions. During vehicle manufacturing, at end of line, or if a Cam/Crank Relearn is performed, the system learns the difference between the Camshaft and Crankshaft position in terms of engine degrees and stores it in the EEPROM. During every following driving cycle, the Powertrain Control Module (PCM) uses this value to compare.

Within a driving cycle, once the CMP position and CKP position are known and verified they are considered "locked." This diagnostic will only run when both sensor signals are in the "locked" state. Engine position is constantly tracked as the CMP Sensor and CKP Sensor signals are monitored by the PCM. An engine rotating at a constant speed would produce engine signals that match the nominal pattern exactly. With engine acceleration and deceleration the engine signals are compressed or stretched in time relative to nominal timing. The PCM takes into account and adjusts for any acceleration/deceleration rates that are in effect.

The misalignment fault accounts for angular deviation between the CMP Sensor and CKP Sensor signals due to miss builds, chain stretch, or skipped tooth. This fault results from the difference between the positions as indicated by the CMP Sensor and CKP Sensor signals. The result is only valid if both positions are "locked".

NOTE: **A missing or erratic CMP or CKP signal cannot cause a Cam/Crank Misalignment fault to set. Replacing either sensor will not fix the vehicle.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft/Crankshaft Misalignment that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	CALLOUT #	RELATED CAM SENSOR DTCS	PHASER/ACTUATOR DTCS	MISALIGNMENT DTCS	COLD START PERF DTCS
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- With the engine running between approximately 500 - 6000 rpm.

- Battery voltage above 11.0 volts.
- Engine coolant temperature above 10B°C (50B°F).
- Engine oil temperature above 10B°C (50B°F).
- After the Camshaft has been commanded to lock pin long enough that lock pin should be attained (more than approximately three seconds).

SET CONDITION

- The difference between the Bank 1 Intake Camshaft position and the Crankshaft position is more than 10.0 degrees.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INCORRECT ENGINE OIL VISCOSITY OR OIL FILTER
CAM/CRANK LEARNED VALUES OUT OF TOLERANCE
ENGINE OIL AERATED OR CONTAMINATED
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
CAMSHAFT 1/1 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT TONE WHEEL MISALIGNED
CAMSHAFT 1/1 PHASER
TIMING SPROCKET ALIGNMENT
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

    No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are the P0340 or P0344 DTCs present?

      Yes

      - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

      No

      - Go To 3
3. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are there any VVT Solenoid Circuit Open or Slow Response DTCs active or pending?

      Yes

      - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

      No

      - Go To 4
4. **VERIFY THE CAM/CRANK LEARNED VALUES ARE WITHIN TOLERANCE**
   1. With the scan tool, read the Cam/Crank Difference Learned values in the Data Display.

      NOTE: When the Cam/Crank Learn is performed the Camshaft position is learned in High Lift and Low Lift modes on the Variable Valve Lift (VVL) equipped engines. The difference between the High Lift and Low Lift learned values should be less than 2B° for each Camshaft.

      NOTE: If the Cam/Crank Difference Learned values are not in the Data Display, go to 5.

      Are the Intake Cam 1 High Lift and Low Lift learned values within 2B° of each other?

      Yes

      - Go To 5

      No

      - With the scan tool perform the **Cam/Crank Relearn** procedure and retest for DTC.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
5. **ENGINE OIL/ENGINE MECHANICAL**

   NOTE: The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.

   - **ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION**

- **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
- **LOW ENGINE OIL LEVEL**
- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**
- **DETERIORATED OR DIRTY OIL**
- **CONTAMINATED ENGINE OIL**
- **INCORRECT ENGINE OIL VISCOSITY**
- **AERATED ENGINE OIL**

1. If any of the above conditions are found, repair as necessary.

   Were any of the above conditions present?

   Yes

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 6

6. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**
   1. Install the applicable adaptor to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
   2. Start the engine and allow it to idle.
   3. Monitor the engine oil pressure reading on the gauge or scan tool.

      NOTE: **If the oil pressure is below 14 psi or oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or Cam/Crank Misalignment DTC.**

   Is the oil pressure reading stable and above 14.0 psi?

   Yes

   - Go To 7

   No

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **VERIFY AN ACTIVE CONDITION BY CHECKING THE CAM PHASER POSITION**

   NOTE: **If a Cam Phaser or Oil Control Valve is stuck, there may also be a Crankshaft/Camshaft Timing Misalignment and/or Multiple Cylinder Misfire DTC present.**

   NOTE: **It may be necessary to drive the vehicle to allow the Cam Phaser to operate normally and then return to lock pin at idle. The purpose is to check for a phaser that may not be responding quick enough and causing this DTC.**

NOTE: **The Cam Phaser slow response fault can take approximately 30 seconds to fail, where as the misalignment fault generally fails within 5-10 seconds.**

1. What to monitor for during the test step:
   - **The phaser not coming back to lock pin at idle.** This his could indicate a faulty phaser or oil control valve that is permanently stuck off lock pin or a Camshaft Position Solenoid that is electrically stuck on.
   - **The actual position lagging or moving slowly toward the desired position.** This could indicate a faulty phaser or tarnished oil control valve that is dragging.
   - **The actual position lagging and then overshooting the desired position** This could indicate a faulty phaser, oil control valve or Camshaft Position Solenoid that is intermittently sticking or binding and then overshoot when the condition goes away.
2. Start the engine and allow the engine to idle.
3. With the scan tool, monitor and compare the Intake Cam 1 **actual** position value with the Intake Cam 1 **desired** position value. After comparing the two values at idle, check and compare the values at several different engine speeds during the following steps.
4. While monitoring the Intake Cam 1 actual position and desired position values:
   - Raise the engine speed quickly and hold steady for up to 30 seconds.
   - Lower the engine speed and hold steady at a level above idle (off of lock pin) for up to 30 seconds.
5. Repeat the above steps multiple times and allow the engine to come back to idle while monitoring the actual position value to verify that the phaser is returning to lock pin position.

   Is the difference between the actual value and the desired value readings more than 10.0 degrees at idle or is the actual value lagging behind or overshooting the desired value?

   Yes, the difference is greater than 10.0 degrees at idle:

   - Go To 8

   Yes, the actual reading is lagging or overshooting when changing the engine speeds indicating a binding or sticking condition:

   - Go To 9

   No

   - Go To 12

8. **DETERMINE IF THE CAM PHASER ISSUE IS ELECTRICAL OR MECHANICAL**
   1. While the engine is at idle, disconnect the Camshaft 1/1 Position Solenoid harness connector.
   2. The Intake Cam 1 actual position value should change to lock pin with the solenoid disconnected. The Intake Cam position should be at approximately 146.0 degrees at lock pin.

      Did the Intake Cam 1 actual value change to lock pin position with the solenoid unplugged?

      Yes

      - Check the (K76) VVT Intake Control 1/1 circuit for a short to voltage. If the circuit is not shorted to voltage, replace the Powertrain Control Module in accordance with the service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

- Go To 9

9. **CHECK THE CAMSHAFT 1/1 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.
    2. Remove the Camshaft 1/1 Position Solenoid.
    3. Inspect the spring loaded spool valve on the Oil Control Valve.

    NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

    4. Push and release the spring loaded spool valve against the return spring with a small punch.

    NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

    Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

    Yes

    - Go To 10

    No

    - Replace the Camshaft 1/1 Oil Control Valve in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK THE CAMSHAFT 1/1 POSITION SOLENOID OPERATION**
    1. Turn the ignition off.
    2. With the solenoid still removed, reconnect the VVT Intake Solenoid 1/1 Camshaft 1/1 Position Solenoid harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the Camshaft 1/1 Position Solenoid on and off several times.

    Does the Camshaft 1/1 Position Solenoid move freely without binding or sticking during actuation?

    Yes

    - Go To 11

    No

    - Replace the Camshaft 1/1 Position Solenoid in accordance with the Service Information.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **VERIFY THAT THE CAMSHAFT 1/1 POSITION SOLENOID IS ABLE TO MOVE THE PHASER**
    1. Exchange the Camshaft 1/1 Position Solenoid with the Camshaft 2/1 Position Solenoid.

NOTE: **The Intake and Exhaust Solenoids should not be interchanged.**

2. Reconnect the solenoid harness connectors.
3. Turn the ignition on.
4. With the scan tool, erase DTCs in the PCM.
5. Test drive the vehicle under the conditions in which the fault was set.
6. With the scan tool, read DTCs.

   Did the DTC move with the solenoid or stay with the original Camshaft?

   Moved with the solenoid:

   - Replace the faulty Camshaft 1/1 Position Solenoid in accordance with the Service Information.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   Stayed with the original camshaft:

   - Go To 12

12. **CHECK THE INTAKE CAMSHAFT 1/1 TONE WHEEL**
    1. Turn the ignition off.
    2. Check the alignment of the CMP Sensor Tone Wheel on the Intake Camshaft in accordance with the service information.

    Is the CMP Sensor Tone Wheel aligned correctly?

    Yes

    - Go To 13

    No

    - Replace the Intake Camshaft Assembly in accordance with the Service Information. . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE TIMING ALIGNMENT**
    1. Verify proper alignment of the Timing Chain and gears in accordance with the Service Information. Also check the Timing Chain Tensioner and Guide for faulty or broken components.

    Were any issue found with the timing alignment or components?

    Yes

    - Perform the appropriate repair in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Replace the Cam Phaser Assembly in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0018-CRANKSHAFT POSITION - CAMSHAFT POSITION CORRELATION BANK 2 SENSOR 1

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

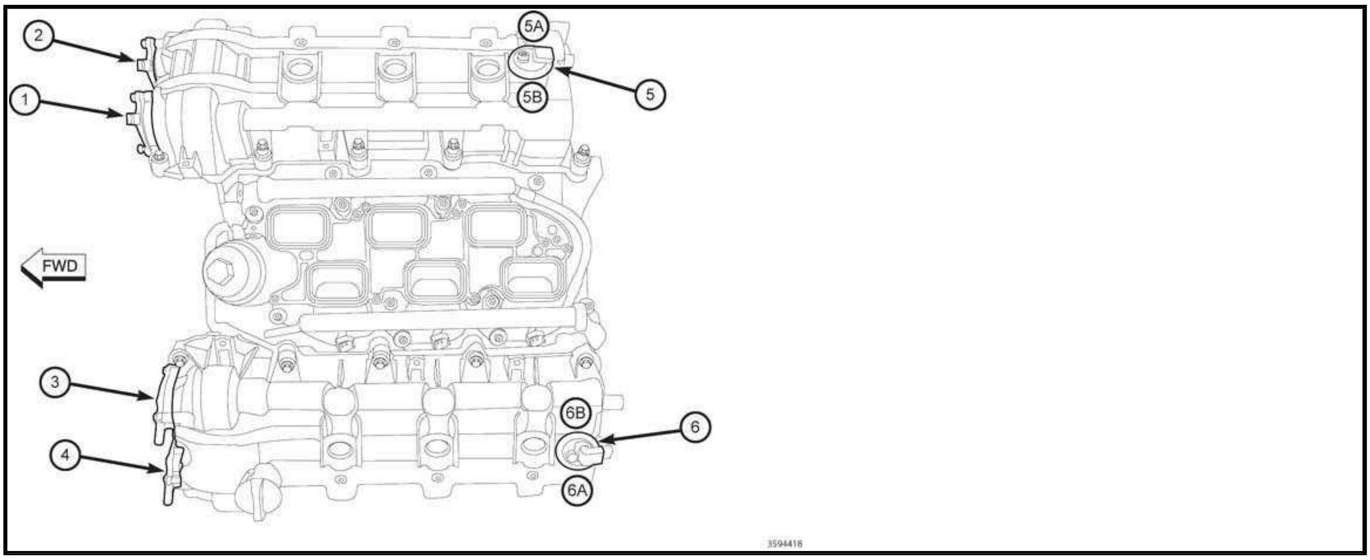
For proper engine control and combustion stability the Camshaft (CMP) and Crankshaft (CKP) positions must be aligned and known so that fuel injection and spark timing can be introduced at the intended Piston and Intake/Exhaust Valve positions. During vehicle manufacturing, at end of line, or if a Cam/Crank Relearn is performed, the system learns the difference between the Camshaft and Crankshaft position in terms of engine degrees and stores it in the EEPROM. During every following driving cycle, the Powertrain Control Module (PCM) uses this value to compare.

Within a driving cycle, once the CMP position and CKP position are known and verified they are considered "locked." This diagnostic will only run when both sensor signals are in the "locked" state. Engine position is constantly tracked as the CMP Sensor and CKP Sensor signals are monitored by the PCM. An engine rotating at a constant speed would produce engine signals that match the nominal pattern exactly. With engine acceleration and deceleration the engine signals are compressed or stretched in time relative to nominal timing. The PCM takes into account and adjusts for any acceleration/deceleration rates that are in effect.

The misalignment fault accounts for angular deviation between the CMP Sensor and CKP Sensor signals due to miss builds, chain stretch, or skipped tooth. This fault results from the difference between the positions as indicated by the CMP Sensor and CKP Sensor signals. The result is only valid if both positions are "locked".

NOTE: **A missing or erratic CMP or CKP signal cannot cause a Cam/Crank Misalignment fault to set. Replacing either sensor will not fix the vehicle.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft/Crankshaft Misalignment that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	**CALLOUT #**	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERF DTCS**
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- During engine cranking.
- With the engine running.
- Battery voltage above 11.0 volts.
- Engine coolant temperature above 10B°C (50B°F).
- Engine oil temperature above 10B°C (50B°F).
- After the Camshaft has been commanded to lock pin long enough that lock pin should be attained (more than approximately three seconds).

SET CONDITION

- The difference between the Bank 2 Exhaust Camshaft position and the Crankshaft position is more than 10.0 degrees.

DEFAULT ACTION

- The MIL will illuminate.

- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INCORRECT ENGINE OIL VISCOSITY OR OIL FILTER
CAM/CRANK LEARNED VALUES OUT OF TOLERANCE
ENGINE OIL AERATED OR CONTAMINATED
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
CAMSHAFT 2/2 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT TONE WHEEL MISALIGNED
CAMSHAFT 2/2 PHASER
TIMING SPROCKET ALIGNMENT
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE DTC**

   NOTE: Perform any Service Bulletins or Star Cases relating to this fault before continuing with this test procedure.

   1. Turn the ignition on.
   2. With the scan tool, read DTCs and record on the repair order.
   3. Record the related Freeze Frame data.
   4. With the scan tool, erase DTCs.
   5. Start the engine and allow it to idle. It maybe necessary to tests drive the vehicle and allow cam phasing to occur in order to reset the fault.

      WARNING: When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.

   6. With the scan tool, read DTCs.

      Is the DTC active or pending?

      Yes

      - Go To 2

      No

      - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are the P0340 or P0344 DTCs present?

Yes

- Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

No

- Go To 3

3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

    Are there any VVT Solenoid Circuit Open or Slow Response DTCs active or pending?

    Yes

    - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

    No

    - Go To 4

4. **VERIFY THE CAM/CRANK LEARNED VALUES ARE WITHIN TOLERANCE**
    1. With the scan tool, read the Cam/Crank Difference Learned values in the Data Display.

    NOTE: **When the Cam/Crank Learn is performed the Camshaft position is learned in High Lift and Low Lift modes on the Variable Valve Lift (VVL) equipped engines. The difference between the High Lift and Low Lift learned values should be less than 2B° for each Camshaft.**

    NOTE: **If the Cam/Crank Difference Learned values are not in the Data Display, go to 5.**

    Are the Exhaust Cam 2 High Lift and Low Lift learned values within 2B° of each other?

    Yes

    - Go To 5

    No

    - With the scan tool perform the **Cam/Crank Relearn** procedure and retest for DTC.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **ENGINE OIL/ENGINE MECHANICAL**

NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

- **ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION**
- **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
- **LOW ENGINE OIL LEVEL**
- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**
- **DETERIORATED OR DIRTY OIL**
- **CONTAMINATED ENGINE OIL**

- **INCORRECT ENGINE OIL VISCOSITY**
- **AERATED ENGINE OIL**

1. If any of the above conditions are found, repair as necessary.

   Were any of the above conditions present?

   Yes

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 6

6. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**
   1. Install the applicable adaptor to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
   2. Start the engine and allow it to idle.
   3. Monitor the engine oil pressure reading on the gauge or scan tool.

   NOTE: **If the oil pressure is below 14 psi or oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or Cam/Crank Misalignment DTC.**

   Is the oil pressure reading stable and above 14.0 psi?

   Yes

   - Go To 7

   No

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **VERIFY AN ACTIVE CONDITION BY CHECKING THE CAM PHASER POSITION**

   NOTE: **If a Cam Phaser or Oil Control Valve is stuck, there may also be a Crankshaft/Camshaft Timing Misalignment and/or Multiple Cylinder Misfire DTC present.**

   NOTE: **It may be necessary to drive the vehicle to allow the Cam Phaser to operate normally and then return to lock pin at idle. The purpose is to check for a phaser that may not be responding quick enough and causing this DTC.**

   NOTE: **The Cam Phaser slow response fault can take approximately 30 seconds to fail, where as the misalignment fault generally fails within 5-10 seconds.**

   1. What to monitor for during the test step:

- **The phaser not coming back to lock pin at idle.** This his could indicate a faulty phaser or oil control valve that is permanently stuck off lock pin or a Camshaft Position Solenoid that is electrically stuck on.
- **The actual position lagging or moving slowly toward the desired position.** This could indicate a faulty phaser or tarnished oil control valve that is dragging.
- **The actual position lagging and then overshooting the desired position** This could indicate a faulty phaser, oil control valve or Camshaft Position Solenoid that is intermittently sticking or binding and then overshoot when the condition goes away.

2. Start the engine and allow the engine to idle.
3. With the scan tool, monitor and compare the Exhaust Cam 2 **actual** position value with the Exhaust Cam 2 **desired** position value. After comparing the two values at idle, check and compare the values at several different engine speeds during the following steps.
4. While monitoring the Exhaust Cam 2 actual position and desired position values:
    - Raise the engine speed quickly and hold steady for up to 30 seconds.
    - Lower the engine speed and hold steady at a level above idle (off of lock pin) for up to 30 seconds.
5. Repeat the above steps multiple times and allow the engine to come back to idle while monitoring the actual position value to verify that the phaser is returning to lock pin position.

   Is the difference between the actual value and the desired value readings more than 10.0 degrees at idle or is the actual value lagging behind or overshooting the desired value?

   Yes, the difference is greater than 10.0 degrees at idle:

   - Go To 8

   Yes, the actual reading is lagging or overshooting when changing the engine speeds indicating a binding or sticking condition:

   - Go To 9

   No

   - Go To 12

8. **DETERMINE IF THE CAM PHASER ISSUE IS ELECTRICAL OR MECHANICAL**
    1. While the engine is at idle, disconnect the Camshaft 2/2 Position Solenoid harness connector.
    2. The Exhaust Cam 2 actual position value should change to lock pin with the solenoid disconnected. The Exhaust Cam position should be at approximately 123.0 degrees at lock pin.

       Did the Exhaust Cam 2 actual value change to lock pin position with the solenoid unplugged?

       Yes

       - Check the (K277) VVT Exhaust Control 2/2 circuit for a short to voltage. If the circuit is not shorted to voltage, replace the Powertrain Control Module in accordance with the service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 9
9. **CHECK THE CAMSHAFT 2/2 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.

2. Remove the Camshaft 2/2 Position Solenoid.
3. Inspect the spring loaded spool valve on the Oil Control Valve.

NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

4. Push and release the spring loaded spool valve against the return spring with a small punch.

NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

Yes

- Go To 10

No

- Replace the Camshaft 2/2 Oil Control Valve in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK THE CAMSHAFT 2/2 POSITION SOLENOID OPERATION**
    1. Turn the ignition off.
    2. With the solenoid still removed, reconnect the Camshaft 2/2 Position Solenoid harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the Camshaft 2/2 Position Solenoid on and off several times.

    Does the Camshaft 2/2 Position Solenoid move freely without binding or sticking during actuation?

    Yes

    - Go To 11

    No

    - Replace the Camshaft 2/2 Position Solenoid in accordance with the Service Information.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **VERIFY THAT THE CAMSHAFT 2/2 POSITION SOLENOID IS ABLE TO MOVE THE PHASER**
    1. Exchange the Camshaft 2/2 Position Solenoid with the Camshaft 1/2 Position Solenoid.

    NOTE: **The Intake and Exhaust Solenoids should not be interchanged.**

    2. Reconnect the solenoid harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs in the PCM.

5. Test drive the vehicle under the conditions in which the fault was set.
6. With the scan tool, read DTCs.

   Did the DTC move with the solenoid or stay with the original Camshaft?

   Moved with the solenoid:

   - Replace the faulty Camshaft 2/2 Position Solenoid in accordance with the Service Information.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   Stayed with the original camshaft:

   - Go To 12

12. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Turn the ignition off.
    2. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    3. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

       Is the CMP Sensor Tone Wheel aligned correctly?

       Yes

       - Go To 13

       No

       - Replace the Exhaust Camshaft Assembly in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE TIMING ALIGNMENT**
    1. Verify proper alignment of the Timing Chain and gears in accordance with the Service Information. Also check the Timing Chain Tensioner and Guide for faulty or broken components.

       Were any issue found with the timing alignment or components?

       Yes

       - Perform the appropriate repair in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

- Replace the Cam Phaser Assembly in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0019-CRANKSHAFT POSITION - CAMSHAFT POSITION CORRELATION BANK 2 SENSOR 2

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

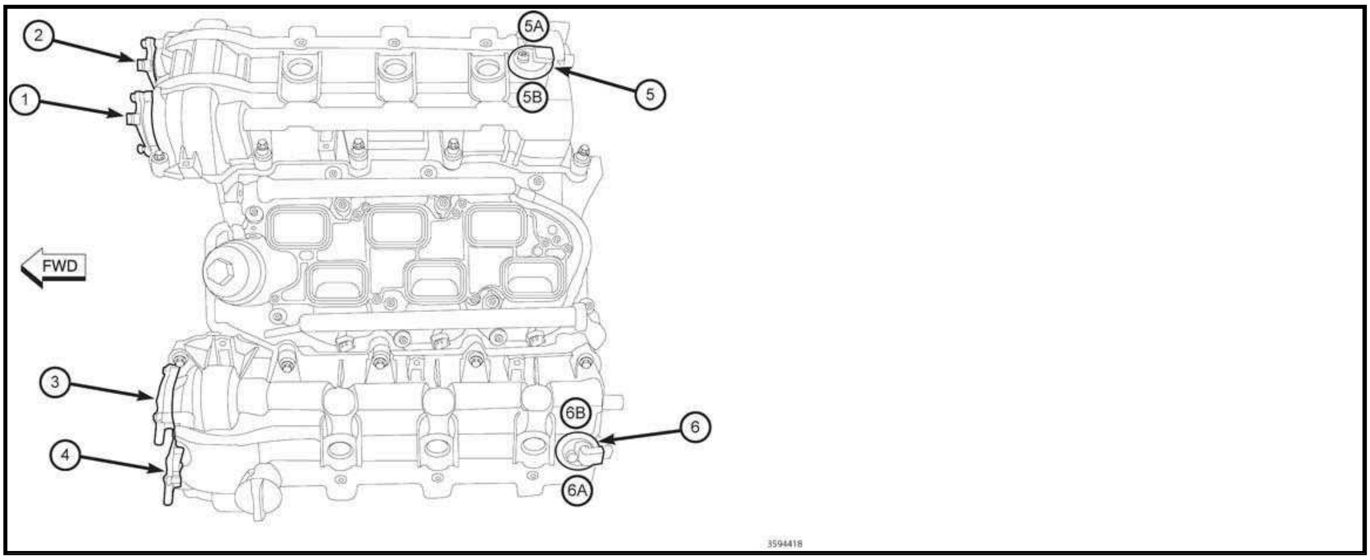
For proper engine control and combustion stability the Camshaft (CMP) and Crankshaft (CKP) positions must be aligned and known so that fuel injection and spark timing can be introduced at the intended Piston and Intake/Exhaust Valve positions. During vehicle manufacturing, at end of line, or if a Cam/Crank Relearn is performed, the system learns the difference between the Camshaft and Crankshaft position in terms of engine degrees and stores it in the EEPROM. During every following driving cycle, the Powertrain Control Module (PCM) uses this value to compare.

Within a driving cycle, once the CMP position and CKP position are known and verified they are considered "locked." This diagnostic will only run when both sensor signals are in the "locked" state. Engine position is constantly tracked as the CMP Sensor and CKP Sensor signals are monitored by the PCM. An engine rotating at a constant speed would produce engine signals that match the nominal pattern exactly. With engine acceleration and deceleration the engine signals are compressed or stretched in time relative to nominal timing. The PCM takes into account and adjusts for any acceleration/deceleration rates that are in effect.

The misalignment fault accounts for angular deviation between the CMP Sensor and CKP Sensor signals due to miss builds, chain stretch, or skipped tooth. This fault results from the difference between the positions as indicated by the CMP Sensor and CKP Sensor signals. The result is only valid if both positions are "locked".

NOTE: **A missing or erratic CMP or CKP signal cannot cause a Cam/Crank Misalignment fault to set. Replacing either sensor will not fix the vehicle.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft/Crankshaft Misalignment that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	**CALLOUT #**	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERF DTCS**
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs continuously when the following condition is met:

- During engine cranking.
- Engine running in closed loop mode.

SET CONDITION

- The difference between the Bank 2 Intake Camshaft position and the Crankshaft position is more than 10.0 degrees.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
INCORRECT ENGINE OIL VISCOSITY OR OIL FILTER
CAM/CRANK LEARNED VALUES OUT OF TOLERANCE
ENGINE OIL AERATED OR CONTAMINATED
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
CAMSHAFT 2/1 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT TONE WHEEL MISALIGNED
CAMSHAFT 2/1 PHASER
TIMING SPROCKET ALIGNMENT
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE DTC**

NOTE: **Perform any Service Bulletins or Star Cases relating to this fault before continuing with this test procedure.**

NOTE: **Diagnose and repair any VVT Solenoid Circuit Open or Slow Response DTCs before continuing with this test.**

1. Turn the ignition on.
2. With the scan tool, read DTCs and record on the repair order.
3. Record the related Freeze Frame data.
4. With the scan tool, erase DTCs.
5. Start the engine and allow it to idle. It maybe necessary to tests drive the vehicle and allow cam phasing to occur in order to reset the fault.

   WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

6. With the scan tool, read DTCs.

   Is the DTC active or pending?

   Yes

   - Go To 2

   No

   - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **VERIFY THE CAM/CRANK LEARNED VALUES ARE WITHIN TOLERANCE**
   1. With the scan tool, read the Cam/Crank Difference Learned values in the Data Display.

      NOTE: **When the Cam/Crank Learn is performed the Camshaft position is learned in High Lift and Low Lift modes on the Variable Valve Lift (VVL) equipped engines. The difference between the High Lift and Low Lift learned values should be less than 2B° for each Camshaft.**

      NOTE: **If the Cam/Crank Difference Learned values are not in the Data Display, go to 3.**

   Are the Intake Cam 2 High Lift and Low Lift learned values within 2B° of each other?

   Yes

   - Go To 3

   No

   - With the scan tool perform the **Cam/Crank Relearn** procedure and retest for DTC.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

3. **ENGINE OIL/ENGINE MECHANICAL**

NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

- **ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION**
- **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
- **LOW ENGINE OIL LEVEL**
- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**
- **DETERIORATED OR DIRTY OIL**
- **CONTAMINATED ENGINE OIL**
- **INCORRECT ENGINE OIL VISCOSITY**
- **AERATED ENGINE OIL**

1. If any of the above conditions are found, repair as necessary.

   Were any of the above conditions present?

   Yes

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 4

4. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**
   1. Install the applicable adaptor to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
   2. Start the engine and allow it to idle.
   3. Monitor the engine oil pressure reading on the gauge or scan tool.

   NOTE: **If the oil pressure is below 14 psi or oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or Cam/Crank Misalignment DTC.**

   Is the oil pressure reading stable and above 14.0 psi?

   Yes

   - Go To 5

   No

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **VERIFY AN ACTIVE CONDITION BY CHECKING THE CAM PHASER POSITION**

NOTE: **If a Cam Phaser or Oil Control Valve is stuck, there may also be a Crankshaft/Camshaft Timing Misalignment and/or Multiple Cylinder Misfire DTC present.**

NOTE: **It may be necessary to drive the vehicle to allow the Cam Phaser to operate normally and then return to lock pin at idle. The purpose is to check for a phaser that may not be responding quick enough and causing this DTC.**

NOTE: **The Cam Phaser slow response fault can take approximately 30 seconds to fail, where as the misalignment fault generally fails within 5-10 seconds.**

1. What to monitor for during the test step:
    - **The phaser not coming back to lock pin at idle.** This his could indicate a faulty phaser or oil control valve that is permanently stuck off lock pin or a Camshaft Position Solenoid that is electrically stuck on.
    - **The actual position lagging or moving slowly toward the desired position.** This could indicate a faulty phaser or tarnished oil control valve that is dragging.
    - **The actual position lagging and then overshooting the desired position** This could indicate a faulty phaser, oil control valve or Camshaft Position Solenoid that is intermittently sticking or binding and then overshoot when the condition goes away.
2. Start the engine and allow the engine to idle.
3. With the scan tool, monitor and compare the Intake Cam 2 **actual** position value with the Intake Cam 2 **desired** position value. After comparing the two values at idle, check and compare the values at several different engine speeds during the following steps.
4. While monitoring the Intake Cam 2 actual position and desired position values:
    - Raise the engine speed quickly and hold steady for up to 30 seconds.
    - Lower the engine speed and hold steady at a level above idle (off of lock pin) for up to 30 seconds.
5. Repeat the above steps multiple times and allow the engine to come back to idle while monitoring the actual position value to verify that the phaser is returning to lock pin position.

    Is the difference between the actual value and the desired value readings more than 10.0 degrees at idle or is the actual value lagging behind or overshooting the desired value?

    Yes, the difference is greater than 10.0 degrees at idle:

    - Go To 6

    Yes, the actual reading is lagging or overshooting when changing the engine speeds indicating a binding or sticking condition:

    - Go To 7

    No

    - Go To 10

6. **DETERMINE IF THE CAM PHASER ISSUE IS ELECTRICAL OR MECHANICAL**
    1. While the engine is at idle, disconnect the Camshaft 2/1 Position Solenoid harness connector.
    2. The Intake Cam 2 actual position value should change to lock pin with the solenoid disconnected. The Intake Cam position should be at approximately 146.0 degrees at lock pin.

        Did the Intake Cam 2 actual value change to lock pin position with the solenoid unplugged?

        Yes

        - Check the (K78) VVT Intake Control 2/1 circuit for a short to voltage. If the circuit is not shorted to voltage, replace the Powertrain Control Module in accordance with the service information.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 7

7. **CHECK THE CAMSHAFT 2/1 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.
    2. Remove the Camshaft 2/1 Position Solenoid.
    3. Inspect the spring loaded spool valve on the Oil Control Valve.

    NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

    4. Push and release the spring loaded spool valve against the return spring with a small punch.

    NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

    Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

    Yes

    - Go To 8

    No

    - Replace the Camshaft 2/1 Oil Control Valve in accordance with the Service Information. . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
8. **CHECK THE CAMSHAFT 2/1 POSITION SOLENOID OPERATION**
    1. Turn the ignition off.
    2. With the solenoid still removed, reconnect the Camshaft 2/1 Position Solenoid harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the Camshaft 2/1 Position Solenoid on and off several times.

    Does the Camshaft 2/1 Position Solenoid move freely without binding or sticking during actuation?

    Yes

    - Go To 9

    No

    - Replace the Camshaft 2/1 Position Solenoid in accordance with the Service Information.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
9. **VERIFY THAT THE CAMSHAFT 2/1 POSITION SOLENOID IS ABLE TO MOVE THE PHASER**

1. Exchange the Camshaft 2/1 Position Solenoid with the Camshaft 1/1 Position Solenoid.

   NOTE: The Intake and Exhaust Solenoids should not be interchanged.

2. Reconnect the solenoid harness connectors.
3. Turn the ignition on.
4. With the scan tool, erase DTCs in the PCM.
5. Test drive the vehicle under the conditions in which the fault was set.
6. With the scan tool, read DTCs.

   Did the DTC move with the solenoid or stay with the original Camshaft?

   Moved with the solenoid:

   - Replace the faulty Camshaft 2/1 Position Solenoid in accordance with the Service Information.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   Stayed with the original camshaft:

   - Go To 10

10. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Turn the ignition off.
    2. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    3. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

       Is the CMP Sensor Tone Wheel aligned correctly?

       Yes

       - Go To 11

       No

       - Replace the Intake Camshaft Assembly in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **CHECK THE ENGINE TIMING ALIGNMENT**
    1. Verify proper alignment of the Timing Chain and gears in accordance with the Service Information. Also check the Timing Chain Tensioner and Guide for faulty or broken components.

       Were any issue found with the timing alignment or components?

       Yes

       - Perform the appropriate repair in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.

No

- Replace the Cam Phaser Assembly in accordance with the Service Information. Refer to PHASER, CAMSHAFT, REMOVAL AND INSTALLATION . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, Flywheel, Valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

P0020-BANK 2 CAMSHAFT 1 POSITION ACTUATOR CIRCUIT OPEN

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Variable Valve Timing (VVT) system continuously varies the Camshaft target position based on the engine operating parameters. Based on these parameters, the Powertrain Control Module (PCM) calculates or models the optimum Camshaft position. The Camshaft angular position is varied by the oil control valve. The VVT solenoid pushes on a plunger (spring loaded spool valve) in the center of the Oil Control Valve (OCV) which directs oil pressure to the hydraulic actuator (Phaser) on the Camshaft Sprocket to change the Camshaft position relative to the Crankshaft position. The VVT Solenoid, acting on the Oil Control Valve and Phaser, is controlled by the PCM. The Camshaft Position (CMP) Sensor is used to monitor the position of the Camshaft.

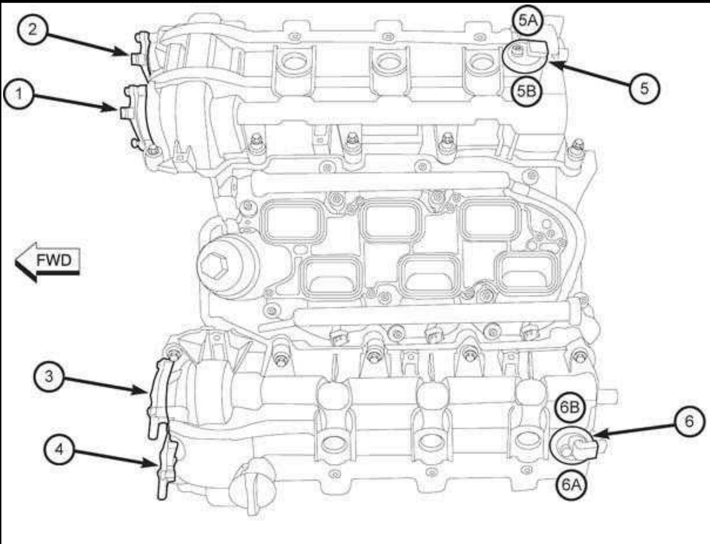
NOTE: **For the PCM to run this diagnostic the CMP Sensor and CKP Sensor signals must be locked with no sensor faults present. A missing or erratic CMP or CKP signal cannot cause a slow response fault to set. Replacing either sensor will not fix the vehicle.**

The PCM performs the typical diagnostic checks on the control circuits. During operation of the system the PCM also performs a **Target Error** and a **Slow Response** diagnostic check of the Camshaft phasing since these conditions could potentially increase tailpipe emissions. The diagnostic is primarily performed by comparing the actual Camshaft position to that of a calculated model for the Camshaft position. This diagnostic is continuous once the enable conditions are met. The Slow Response and Target Error conditions are not performed simultaneously.

- **The Target Error** diagnostic evaluates the actual Camshaft position versus the modeled position when the Camshaft is in a relatively stable position. The difference between the two is considered to be the amount of "error". If the error amount is greater than a calibrated threshold, it is considered failing.
- **The Slow Response** diagnostic is only performed when the modeled Camshaft position is moving (phasing) in a particular direction, advancing or retarding. The modeled Camshaft phasing position is created to match only the worst possible case of a passing Camshaft position. If the actual Camshaft phasing operates slower than the model by a calibrated threshold, it is considered failing.

If either of these diagnostics fail, the Camshaft Position Slow Response fault will set. **Any oil pressure issues, VVT Solenoid or Oil Pump Solenoid Control circuit faults should be diagnosed before diagnosing a Camshaft Position Slow Response fault.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft Position Slow Response that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT				
CAMSHAFT POSITION	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERF DTCS**
(1) Bank 1 Intake Camshaft	P0365, P0369	P000A, P0010	P0017	P052A, P052B
(2) Bank 1 Exhaust Camshaft	P0340, P0344	P000B, P0013	P0016	P054A, P054B
(3) Bank 2 Intake Camshaft	P0390, P0394	P000C, P0020	P0019	P052C, P052D
(4) Bank 2 Exhaust Camshaft	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage greater than 10.4 volts.

SET CONDITION

- The PCM has detected a circuit failure on the VVT Intake Solenoid 2/1 Control circuitry.

DEFAULT ACTION

- The MIL will illuminate.
- The stop/start system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
VVT INTAKE SOLENOID 2/1 CONTROL CIRCUIT SHORTED TO GROUND
VVT INTAKE SOLENOID 2/1 CONTROL CIRCUIT SHORTED TO VOLTAGE

Possible Causes
VVT INTAKE SOLENOID 2/1 SOLENOID CONTROL CIRCUIT OPEN/HIGH RESISTANCE
VVT INTAKE SOLENOID 2/1 SOLENOID GROUND CIRCUIT OPEN/HIGH RESISTANCE
VVT INTAKE SOLENOID 2/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK THE VVT INTAKE SOLENOID 2/1 CONNECTOR AND TERMINALS**
    1. Turn the ignition off.
    2. Check the VVT Intake Solenoid 2/1 harness connector for proper connection at the VVT Intake Solenoid 2/1.
    3. Verify that the connector is completely plugged in and properly locked prior to disconnecting.

4. Disconnect the VVT Intake Solenoid 2/1 harness connector and check for any pushed out, damaged or spread terminals.

   Were any issues found with the connector or terminals?

   Yes

   - Repair the damaged terminal or properly connect and lock the VVT Intake Solenoid 2/1 harness connector and retest for DTCs.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 4

4. **ISOLATE AND CHECK THE VVT INTAKE SOLENOID 2/1 (K78) CONTROL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5

5. **ISOLATE AND CHECK THE VVT INTAKE SOLENOID 2/1 (K78) CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.

4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK THE (Z904) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
   1. Disconnect the component harness connector to isolate the ground circuit.
   2. Connect the positive lead of the load test tool to the positive side of the Battery.
   3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
   4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

NOTE: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .

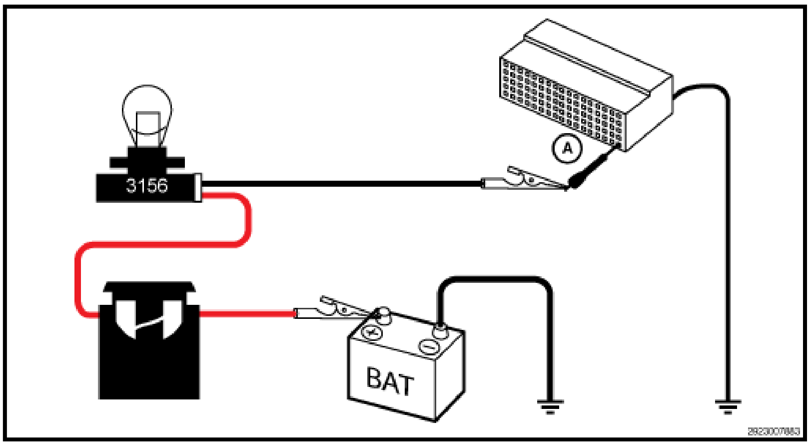
NOTE: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**

- 3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 7

   No

   - Repair the ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

7. **ISOLATE AND LOAD TEST THE VVT INTAKE SOLENOID 2/1 (K78) CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
   1. The ignition must be off when performing a load test on a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.

3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

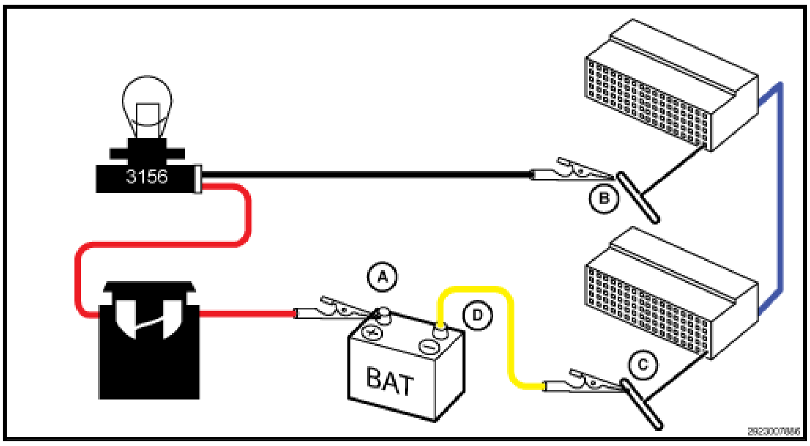
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to** **CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
- **3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to **CIRCUIT LOAD TESTING PROCEDURES .**



WARNING: **To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.**

CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 8

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. ACTUATE AND CHECK THE OPERATION OF THE VVT INTAKE SOLENOID 2/1 DRIVER
   1. Reconnect the PCM C2 harness connector.
   2. Turn the ignition on.
   3. Using a 12-volt test light connected to ground, probe the VVT Intake Solenoid 2/1 (K78) Control circuit in the VVT Intake Solenoid 2/1 harness connector.

NOTE: **The PCM will command the solenoid ON briefly after the ignition is turned on. This is a normal condition. The test light will illuminate briefly and then turn off and stay off if there is not a short to voltage.**

4. With the scan tool, actuate the VVT Intake Solenoid 2/1 Control to the highest duty cycle (80%) position.

   NOTE: **The test light should be illuminated and bright or illuminate with a steady pulse.**

   Is the test light illuminated and bright or illuminate with a steady pulse?

   Yes

   - Replace the VVT Intake Solenoid 2/1 in accordance with the Service Information. .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.
   6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   9. With the scan tool, erase DTCs.
   10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
   11. With the scan tool, read DTCs.

   Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0023-BANK 2 CAMSHAFT 2 POSITION ACTUATOR CIRCUIT OPEN

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Variable Valve Timing (VVT) system continuously varies the Camshaft target position based on the engine operating parameters. Based on these parameters, the Powertrain Control Module (PCM) calculates or models the optimum Camshaft position. The Camshaft angular position is varied by the oil control valve. The VVT solenoid pushes on a plunger (spring loaded spool valve) in the center of the Oil Control Valve (OCV) which directs oil pressure to the hydraulic actuator (Phaser) on the Camshaft Sprocket to change the Camshaft position relative to the Crankshaft position. The VVT Solenoid, acting on the Oil Control Valve and Phaser, is controlled by the PCM. The Camshaft Position (CMP) Sensor is used to monitor the position of the Camshaft.

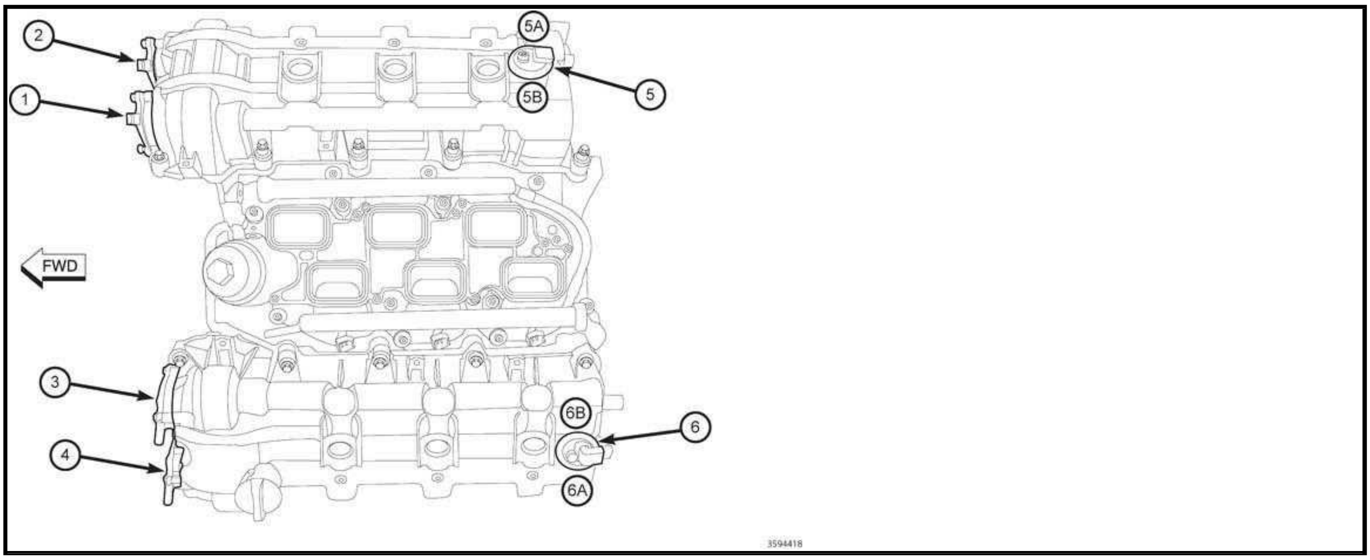
NOTE: **For the PCM to run this diagnostic the CMP Sensor and CKP Sensor signals must be locked with no sensor faults present. A missing or erratic CMP or CKP signal cannot cause a slow response fault to set. Replacing either sensor will not fix the vehicle.**

The PCM performs the typical diagnostic checks on the control circuits. During operation of the system the PCM also performs a **Target Error** and a **Slow Response** diagnostic check of the Camshaft phasing since these conditions could potentially increase tailpipe emissions. The diagnostic is primarily performed by comparing the actual Camshaft position to that of a calculated model for the Camshaft position. This diagnostic is continuous once the enable conditions are met. The Slow Response and Target Error conditions are not performed simultaneously.

- **The Target Error** diagnostic evaluates the actual Camshaft position versus the modeled position when the Camshaft is in a relatively stable position. The difference between the two is considered to be the amount of "error". If the error amount is greater than a calibrated threshold, it is considered failing.
- **The Slow Response** diagnostic is only performed when the modeled Camshaft position is moving (phasing) in a particular direction, advancing or retarding. The modeled Camshaft phasing position is created to match only the worst possible case of a passing Camshaft position. If the actual Camshaft phasing operates slower than the model by a calibrated threshold, it is considered failing.

If either of these diagnostics fail, the Camshaft Position Slow Response fault will set. **Any oil pressure issues, VVT Solenoid or Oil Pump Solenoid Control circuit faults should be diagnosed before diagnosing a Camshaft Position Slow Response fault.**

NOTE: **On occasion a small piece of debris or metal chip can get lodged in the OCV causing the spool valve to stick. The contamination can either dislodge on it's own or when the PCM is running a cleaning procedure on the OCV causing an intermittent fault condition for a Camshaft Position Slow Response that is no longer present.**



NOTE: **There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and table below indicating the specific orientation of the DTCs to the Camshafts).**

3.2L/3.6L DTCs RELATED TO EACH CAMSHAFT				
CAMSHAFT POSITION	RELATED CAM SENSOR DTCS	PHASER/ACTUATOR DTCS	MISALIGNMENT DTCS	COLD START PERF DTCS
(1) Bank 1 Intake Camshaft	P0365, P0369	P000A, P0010	P0017	P052A, P052B
(2) Bank 1 Exhaust Camshaft	P0340, P0344	P000B, P0013	P0016	P054A, P054B
(3) Bank 2 Intake Camshaft	P0390, P0394	P000C, P0020	P0019	P052C, P052D
(4) Bank 2 Exhaust Camshaft	P0345, P0349	P000D, P0023	P0018	P054C, P054D

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage greater than 10.4 volts.

SET CONDITION

- The PCM has detected a circuit failure on the VVT Exhaust Solenoid 2/2 Control circuitry.

DEFAULT ACTION

- The MIL will illuminate.
- The stop/start system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
VVT EXHAUST SOLENOID 2/2 CONTROL CIRCUIT SHORTED TO GROUND
VVT EXHAUST SOLENOID 2/2 CONTROL CIRCUIT SHORTED TO VOLTAGE

Possible Causes
VVT EXHAUST SOLENOID 2/2 CONTROL CIRCUIT OPEN/HIGH RESISTANCE
VVT EXHAUST SOLENOID 2/2 GROUND CIRCUIT OPEN/HIGH RESISTANCE
VVT EXHAUST SOLENOID 2/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK THE VVT EXHAUST SOLENOID 2/2 CONNECTOR AND TERMINALS**
    1. Turn the ignition off.
    2. Check the VVT Exhaust Solenoid 2/2 harness connector for proper connection at the VVT Exhaust Solenoid 2/2.
    3. Verify that the connector is completely plugged in and properly locked prior to disconnecting.

4. Disconnect the VVT Exhaust Solenoid 2/2 harness connector and check for any pushed out, damaged or spread terminals.

   Were any issues found with the connector or terminals?

   Yes

   - Repair the damaged terminal or properly connect and lock the VVT Exhaust Solenoid 2/2 harness connector and retest for DTCs.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 4

4. **ISOLATE AND CHECK THE VVT EXHAUST SOLENOID 2/2 (K277) CONTROL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

      NOTE: **There should be no continuity between ground and the circuit being tested.**

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5

5. **ISOLATE AND CHECK THE VVT EXHAUST SOLENOID 2/2 (K277) CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.

4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK THE (Z904) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
   1. Disconnect the component harness connector to isolate the ground circuit.
   2. Connect the positive lead of the load test tool to the positive side of the Battery.
   3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
   4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

NOTE: **Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

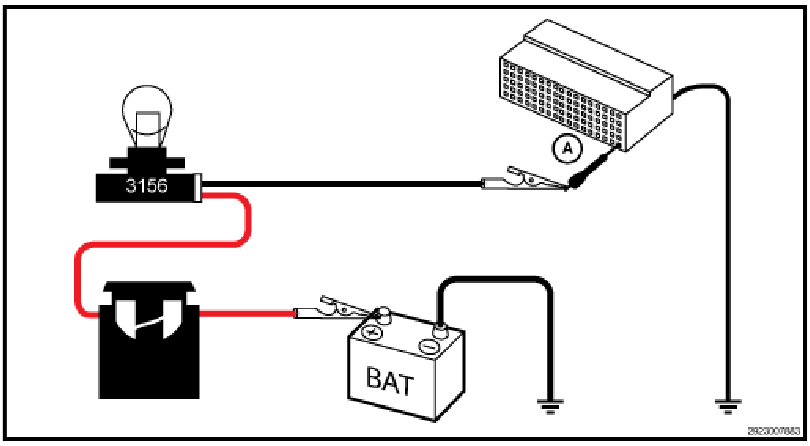
NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**

- 3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 7

   No

   - Repair the ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

7. **ISOLATE AND LOAD TEST THE VVT EXHAUST SOLENOID 2/2 (K277) CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
   1. The ignition must be off when performing a load test on a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.

3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

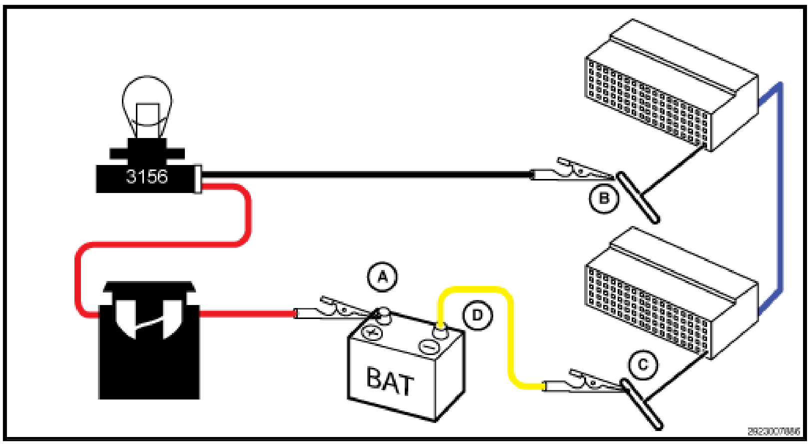
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
- **3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: **To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.**

CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 8

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **ACTUATE AND CHECK THE OPERATION OF THE VVT EXHAUST SOLENOID 2/2 DRIVER**
   1. Reconnect the PCM C2 harness connector.
   2. Turn the ignition on.
   3. Using a 12-volt test light connected to ground, probe the VVT Exhaust Solenoid 2/2 (K277) Control circuit in the VVT Exhaust Solenoid 2/2 harness connector.

NOTE: **The PCM will command the solenoid ON briefly after the ignition is turned on. This is a normal condition. The test light will illuminate briefly and then turn off and stay off if there is not a short to voltage.**

4. With the scan tool, actuate the VVT Exhaust Solenoid 2/2 Control to the highest duty cycle (80%) position.

   NOTE: **The test light should be illuminated and bright or illuminate with a steady pulse.**

   Is the test light illuminated and bright or illuminate with a steady pulse?

   Yes

   - Replace the VVT Exhaust Solenoid 2/2 in accordance with the Service Information. .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.

   6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   9. With the scan tool, erase DTCs.
   10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
   11. With the scan tool, read DTCs.

   Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0031-O2 SENSOR 1/1 HEATER CIRCUIT LOW

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature**

Using the Scan Tool for Diagnostics:	
	will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to

Using the Scan Tool for Diagnostics:	
	ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

- Continuously with the O2 Sensor heater commanded on.
- Battery voltage between 10.5 and 15.75 volts.
- DTC P0032 is not active.

SET CONDITION

- The PCM detects that the O2 Sensor heater circuit resistance is below approximately 2.0 Ohms.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/1 HEATER CONTROL CIRCUIT SHORTED TO GROUND
O2 SENSOR 1/1 HEATER CONTROL CIRCUIT SHORTED TO THE O2 SENSOR GROUND CIRCUIT
OXYGEN (O2) SENSOR 1/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. With the scan tool, run a vehicle Scan Report or record the Environmental Data related to the DTCs.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the recorded Environmental Data and the When Monitored Conditions above, operate the vehicle in the conditions that set the DTC.

7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K99) HEATER CONTROL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 3

3. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K99) HEATER CONTROL CIRCUIT FOR A SHORT TO THE (Z910) GROUND CIRCUIT**
   1. The ignition must be off when checking for a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.

3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

NOTE: **There should be no continuity between the circuits being tested.**

Is there continuity between the circuits?

Yes

- Repair the short between the circuits.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 4

4. **CHECK THE O2 SENSOR 1/1 (K99) HEATER CONTROL CIRCUIT**
   1. Reconnect the PCM harness connector.
   2. Turn the ignition on.
   3. With the scan tool, actuate the O2 Sensor 1/2 control to the maximum allowable percentage.
   4. Using a 12-volt test light connected to ground, probe the O2 Sensor 1/1 (K99) Heater Control circuit at the O2 Sensor 1/2 harness connector.

   NOTE: **The test light should be illuminated. The brightness will be dependant on the actuation percentage selected.**

   5. With the scan tool, actuate the O2 Sensor 1/2 control to the OFF (0%) position.

   NOTE: **The test light should not be illuminated.**

   Does the test light illuminate with the actuator ON and not illuminate with the actuator OFF?

   Yes

   - Replace the O2 Sensor 1/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5
5. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.

2. Disconnect all PCM harness connectors.
3. Disconnect all related in-line harness connections (if equipped).
4. Disconnect the related component harness connectors.
5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
    - Proper connector installation.
    - Damaged connector locks.
    - Corrosion.
    - Other signs of water intrusion.
    - Weather seal damage (if equipped).
    - Bent terminals.
    - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
    - Terminals that have been pushed back into the connector cavity.
    - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0032-O2-SENSOR 1/1 HEATER CIRCUIT HIGH

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause

the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool.

NOTE:

When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance,

Using the Scan Tool for Diagnostics:	
	will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Continuously with the O2 Sensor heater commanded on.
- Battery voltage between 10.5 and 15.75 volts.
- DTC P0031 is not active.

SET CONDITION

- When the PCM detects that the O2 Sensor 1/1 Heater circuit resistance is above approximately 35.0 Ohms.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/1 HEATER CONTROL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 1/1 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
OXYGEN (O2) SENSOR 1/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. With the scan tool, run a vehicle Scan Report or record the Environmental Data related to the DTCs.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the recorded Environmental Data and the When Monitored Conditions above, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **CHECK THE (Z910) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
    1. Disconnect the component harness connector to isolate the ground circuit.
    2. Connect the positive lead of the load test tool to the positive side of the Battery.
    3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
    4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

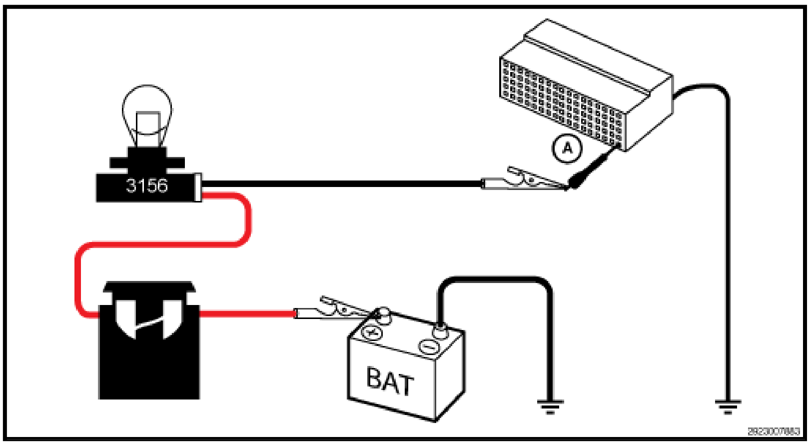
NOTE: **Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
- **3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 4

   No

   - Repair the ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

4. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K99) HEATER CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
   4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

   Is there continuity between the circuit being tested and any other circuit?

   Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K99) HEATER CONTROL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 6

    No

    - Repair the circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
6. **CHECK THE PCM HEATER CONTROL DRIVER FOR PROPER OPERATION**
    1. Turn the ignition off.
    2. Reconnect the PCM C2 harness connector.
    3. Turn the ignition on.
    4. Using a 12-volt test light connected to ground, probe the O2 Sensor 1/1 (K99) Heater Control circuit in the O2 Sensor 1/1 harness connector.
    5. With the scan tool, actuate the O2 Sensor 1/1 control to the maximum allowable percentage.

    NOTE: **The test light should be illuminated. The brightness will be dependant on the actuation percentage selected.**

6. With the scan tool, actuate the O2 Sensor 1/1 control to the OFF (0%) position.

   NOTE: The test light should not be illuminated.

   Does the test light illuminate with the actuator ON and not illuminated with the actuator OFF (0%)?

   Yes

   - Replace the O2 Sensor 1/1 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 7

7. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.

   6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   9. With the scan tool, erase DTCs.
   10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
   11. With the scan tool, read DTCs.

       Did the DTC return?

       Yes

       - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND**

INSTALLATION .

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0037-O2-SENSOR 1/2 HEATER CIRCUIT LOW

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool.**

Using the Scan Tool for Diagnostics:

	If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.

Using the Scan Tool for Diagnostics:	
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Battery voltage between 10.5 and 15.75 volts.
- The O2 Sensor Heater is commanded on.
- The O2 Sensor Heater circuit high fault is not active.

SET CONDITION

- The PCM detects that the O2 Sensor heater circuit resistance is below approximately 2.0 Ohms.

DEFAULT ACTION

- The MIL will illuminate.
- The PCM will disable the O2 Sensor Heater driver for the remainder of this ignition cycle.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/2 HEATER CONTROL CIRCUIT SHORTED TO GROUND
O2 SENSOR 1/2 HEATER CONTROL CIRCUIT SHORTED TO THE O2 SENSOR GROUND CIRCUIT
O2 SENSOR 1/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. With the scan tool, run a vehicle Scan Report or record the Environmental Data related to the DTCs.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the recorded Environmental Data and the When Monitored Conditions above, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **ISOLATE AND CHECK THE O2 SENSOR 1/2 (K299) HEATER CONTROL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

    NOTE: **There should be no continuity between ground and the circuit being tested.**

    Is there continuity between ground and the circuit being tested?

    Yes

    - Repair the O2 Sensor 1/2 (K299) Heater Control circuit for a short to chassis ground or the O2 Sensor (Z910) Ground circuit. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 4
4. **CHECK THE O2 SENSOR 1/2 (K299) HEATER CONTROL CIRCUIT OPERATION**
    1. Reconnect the PCM harness connector.
    2. Turn the ignition on.
    3. With the scan tool, actuate the O2 Sensor 1/2 control to the maximum allowable percentage.

4. Using a 12-volt test light connected to ground, probe the O2 Sensor 1/2 (K299) Heater Control circuit at the O2 Sensor 1/2 harness connector.

   NOTE: **The test light should be illuminated. The brightness will be dependant on the actuation percentage selected.**

5. With the scan tool, actuate the O2 Sensor 1/2 control to the OFF (0%) position.
6. Using a 12-volt test light connected to ground, probe the O2 Sensor 1/2 (K299) Heater Control circuit at the O2 Sensor 1/2 harness connector.

   NOTE: **The test light should not be illuminated.**

   Does the test light illuminate with the actuator ON and not illuminate with the actuator OFF?

   Yes

   - Replace the O2 Sensor 1/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5

5. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.

   6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   9. With the scan tool, erase DTCs.
   10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.

11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0038-O2-SENSOR 1/2 HEATER CIRCUIT HIGH

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within

the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50**

	percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will

Using the Scan Tool for Diagnostics:	
(Return) Circuit Low Diagnosis:	switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Battery voltage between 10.5 and 15.75 volts.
- O2 Sensor Heater commanded on.
- The O2 Sensor Heater circuit low fault is not active.

SET CONDITION

- When the Powertrain Control Module (PCM) detects that the O2 Sensor 1/2 Heater circuit resistance is above approximately 35.0 Ohms.

DEFAULT ACTION

- The MIL will illuminate.
- The PCM will disable the O2 Sensor Heater driver for the remainder of this ignition cycle.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/2 HEATER CONTROL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 1/2 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
OXYGEN SENSOR 1/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

- Perform the applicable repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
   1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
   2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
   3. With the scan tool, erase all DTCs.
   4. Turn the ignition off for a minimum of 10.0 seconds.
   5. Turn the ignition on.
   6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
   7. With the scan tool, read DTCs.

   Did the DTC return?

   Yes

   - Go To 3

   No

   - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK THE (Z910) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
   1. Disconnect the component harness connector to isolate the ground circuit.
   2. Connect the positive lead of the load test tool to the positive side of the Battery.
   3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
   4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

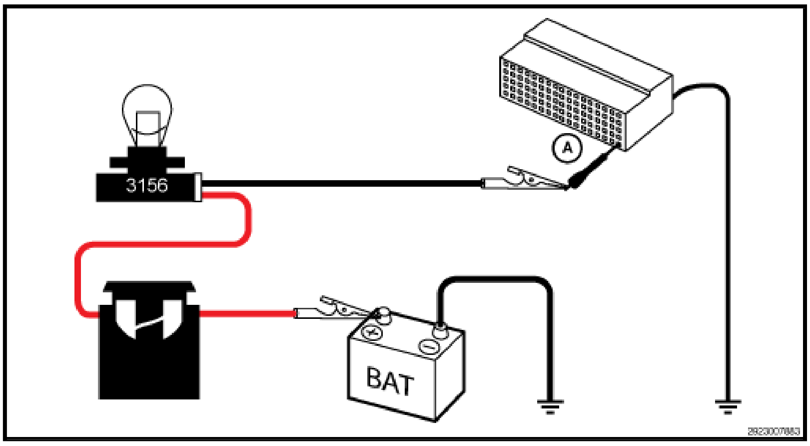
NOTE:	**Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**
NOTE:	**A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a**

circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 4

No

- Repair the ground circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND CHECK THE O2 SENSOR 1/2 (K299) HEATER CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

        NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

    Is there continuity between the circuit being tested and any other circuit?

    Yes

    - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 5

5. **ISOLATE AND LOAD TEST THE O2 SENSOR 1/2 (K299) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
    1. The ignition must be off when performing a load test on a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
    3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
    4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at one of the component harness connectors (B).
    5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
    6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

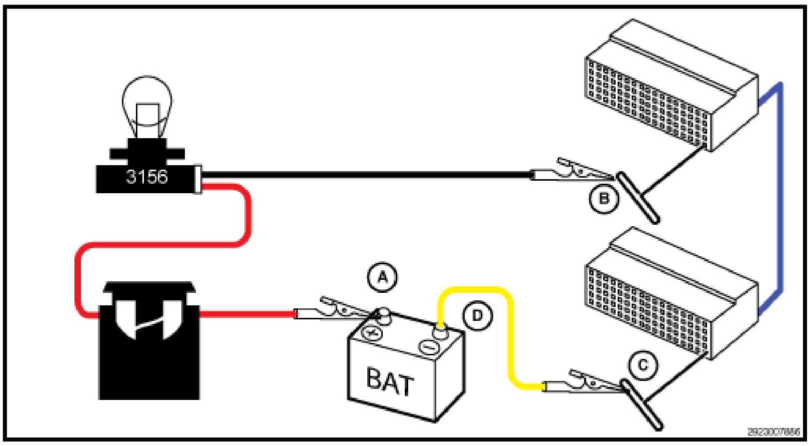
NOTE: Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .

NOTE: Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: Do not load test any circuits with components still connected to the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 6

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE O2 SENSOR 1/2 HEATER CONTROL DRIVER FOR PROPER OPERATION**
   1. Turn the ignition off.
   2. Connect the PCM C2 harness connector.
   3. Turn the ignition on.
   4. With the scan tool, actuate the O2 Sensor 1/2 control to the maximum allowable percentage.
   5. Using a 12-volt test light connected to ground, check the O2 Sensor 1/2 (K299) Heater Control circuit at the O2 Sensor 1/2 harness connector.

      NOTE: **The test light should be illuminated. The brightness will be dependant on the actuation percentage selected.**

   6. With the scan tool, actuate the O2 Sensor 1/2 control to the OFF (0%) position.

      NOTE: **The test light should not be illuminated.**

   Does the test light illuminate with the actuator ON and not illuminated with the actuator OFF (0%)?

   Yes

   - Replace the O2 Sensor 1/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 7

7. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.

2. Disconnect all PCM harness connectors.
3. Disconnect all related in-line harness connections (if equipped).
4. Disconnect the related component harness connectors.
5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
    - Proper connector installation.
    - Damaged connector locks.
    - Corrosion.
    - Other signs of water intrusion.
    - Weather seal damage (if equipped).
    - Bent terminals.
    - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
    - Terminals that have been pushed back into the connector cavity.
    - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0051-O2-SENSOR 2/1 HEATER CIRCUIT LOW

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause

the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool.

NOTE:

When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance,

Using the Scan Tool for Diagnostics:	
	will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

- Battery voltage between 10.5 and 15.75 volts.
- The O2 Sensor Heater is commanded on.
- The O2 Sensor Heater circuit high fault is not active.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the O2 Sensor heater circuit resistance is below approximately 2.0 Ohms.

DEFAULT ACTION

- The MIL will illuminate.
- The PCM will disable the O2 Sensor Heater driver for the remainder of this ignition cycle.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/1 HEATER CONTROL CIRCUIT SHORTED TO GROUND
O2 SENSOR 2/1 HEATER CONTROL CIRCUIT SHORTED TO THE O2 SENSOR GROUND CIRCUIT
O2 SENSOR 2/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To3

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K199) HEATER CONTROL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the O2 Sensor 2/1 (K199) Heater Control circuit for a short to chassis ground or the O2 Sensor (Z910) Ground circuit. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 4

4. **CHECK THE O2 SENSOR 2/1 HEATER CONTROL CIRCUIT**
    1. Turn the ignition off.
    2. Reconnect the PCM harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the O2 Sensor 2/1 control to the maximum allowable percentage.
    5. Using a 12-volt test light connected to ground, probe the O2 Sensor 2/1 (K199) Heater Control circuit at the O2 Sensor 2/1 harness connector.

    NOTE: **The test light should be illuminated. The brightness will be dependant on the actuation percentage selected.**

    6. With the scan tool, actuate the O2 Sensor 2/1 control to the OFF (0%) position.
    7. Using a 12-volt test light connected to ground, probe the O2 Sensor 2/1 (K199) Heater Control circuit at the O2 Sensor 2/1 harness connector.

    NOTE: **The test light should not be illuminated.**

    Does the test light illuminate with the actuator ON and not illuminate with the actuator OFF?

    Yes

    - Replace the O2 Sensor 2/1 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0052-O2-SENSOR 2/1 HEATER CIRCUIT HIGH

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any**

	issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

- Battery voltage between 10.5 and 15.75 volts.
- O2 Sensor Heater commanded on.
- The O2 Sensor Heater circuit low fault is not active.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the O2 Sensor 2/1 Heater circuit resistance is above approximately 35.0 Ohms.

DEFAULT ACTION

- The MIL will illuminate.
- The PCM will disable the O2 Sensor Heater driver for the remainder of this ignition cycle.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/1 HEATER CONTROL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 2/1 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/1 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

        Are there any applicable Service Bulletins or Flash updates?

        Yes

        - Perform the applicable repair.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 3

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **CHECK THE (Z910) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
   1. Disconnect the component harness connector to isolate the ground circuit.
   2. Connect the positive lead of the load test tool to the positive side of the Battery.
   3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
   4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

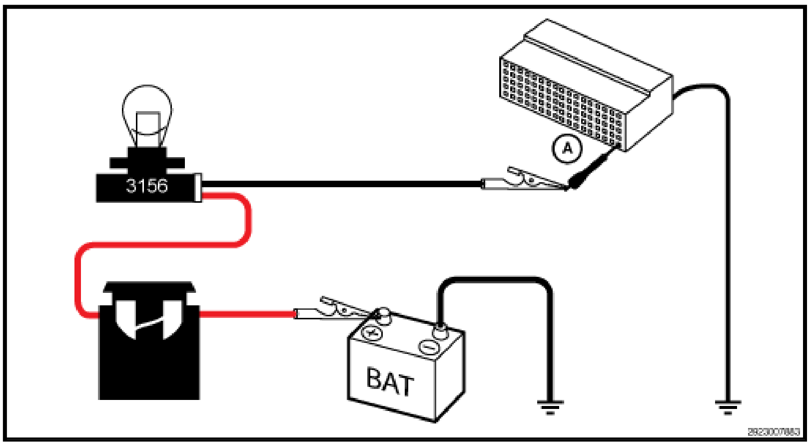
NOTE: **Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

Is the load test bulb illuminated and bright?

Yes

- Go To 4

No

- Repair the ground circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K399) HEATER CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **ISOLATE AND LOAD TEST THE O2 SENSOR 2/2 (K399) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
    1. The ignition must be off when performing a load test on a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
    3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
    4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at one of the component harness connectors (B).
    5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
    6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

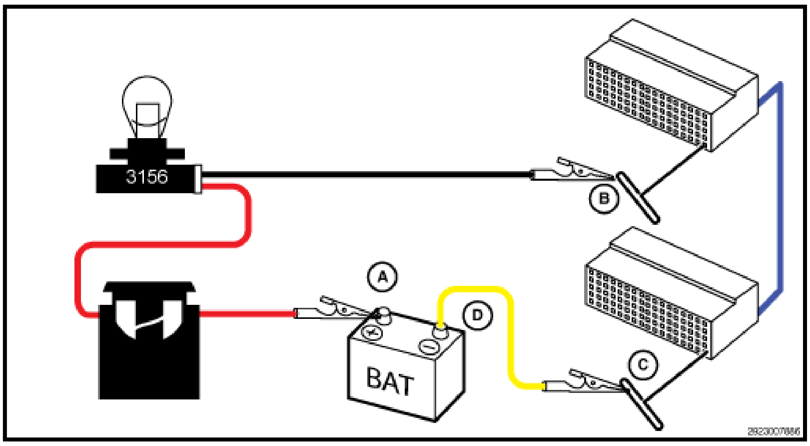
NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**

2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

Is the load test bulb illuminated and bright?

Yes

- Go To 6

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE O2 SENSOR 2/2 HEATER CONTROL DRIVER FOR PROPER OPERATION**
    1. Turn the ignition off.
    2. Connect the PCM C2 harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the O2 Sensor 2/2 control to the maximum allowable percentage.
    5. Using a 12-volt test light connected to ground, check the O2 Sensor 2/2 (K399) Heater Control circuit at the O2 Sensor 2/2 harness connector.

        NOTE: **The test light should be illuminated. The brightness will be dependant on the actuation percentage selected.**

    6. With the scan tool, actuate the O2 Sensor 2/2 control to the OFF (0%) position.

        NOTE: **The test light should not be illuminated.**

        Does the test light illuminate with the actuator ON and not illuminated with the actuator OFF (0%)?

        Yes

        - Replace the O2 Sensor 2/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Go To 7
7. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.

8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0057-O2 SENSOR 2/2 HEATER CIRCUIT LOW

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM.

Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.

- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. NOTE: **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage**

	will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it

Using the Scan Tool for Diagnostics:	
	could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

- Battery voltage between 10.5 and 15.75 volts.
- The O2 Sensor Heater is commanded on.
- The O2 Sensor Heater circuit high fault is not active.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the O2 Sensor heater circuit resistance is below approximately 2.0 Ohms.

DEFAULT ACTION

- The MIL will illuminate.
- The PCM will disable the O2 Sensor Heater driver for the remainder of this ignition cycle.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/2 HEATER CONTROL CIRCUIT SHORTED TO GROUND
O2 SENSOR 2/2 HEATER CONTROL CIRCUIT SHORTED TO THE O2 SENSOR GROUND CIRCUIT
O2 SENSOR 2/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

Are there any applicable Service Bulletins or Flash updates?

Yes

- Perform the applicable repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K399) HEATER CONTROL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

    NOTE: **There should be no continuity between ground and the circuit being tested.**

    Is there continuity between ground and the circuit being tested?

    Yes

    - Repair the O2 Sensor 2/2 (K399) Heater Control circuit for a short to chassis ground or the O2 Sensor (Z910) Ground circuit.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 4

4. **CHECK THE O2 SENSOR 2/2 HEATER CONTROL CIRCUIT**
    1. Turn the ignition off.
    2. Reconnect the PCM harness connector.
    3. Turn the ignition on.
    4. With the scan tool, actuate the O2 Sensor 2/2 control to the maximum allowable percentage.
    5. Using a 12-volt test light connected to ground, probe the O2 Sensor 2/2 (K399) Heater Control circuit at the O2 Sensor 2/2 harness connector.

       NOTE: **The test light should be illuminated. The brightness will be dependant on the actuation percentage selected.**

    6. With the scan tool, actuate the O2 Sensor 2/2 control to the OFF (0%) position.
    7. Using a 12-volt test light connected to ground, probe the O2 Sensor 2/2 (K399) Heater Control circuit at the O2 Sensor 2/2 harness connector.

       NOTE: **The test light should not be illuminated.**

    Does the test light illuminate with the actuator ON and not illuminate with the actuator OFF?

    Yes

    - Replace the O2 Sensor 2/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 5

5. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0058-O2-SENSOR 2/2 HEATER CIRCUIT HIGH

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to**

	operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor

Using the Scan Tool for Diagnostics:	
	return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Battery voltage between 10.5 and 15.75 volts.
- O2 Sensor Heater commanded on.
- The O2 Sensor Heater circuit low fault is not active.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the O2 Sensor 2/2 Heater circuit resistance is above approximately 35.0 Ohms.

DEFAULT ACTION

- The MIL will illuminate.
- The PCM will disable the O2 Sensor Heater driver for the remainder of this ignition cycle.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/2 HEATER CONTROL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 2/2 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/2 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK THE (Z910) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
    1. Disconnect the component harness connector to isolate the ground circuit.
    2. Connect the positive lead of the load test tool to the positive side of the Battery.
    3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
    4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

NOTE:	**Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load**

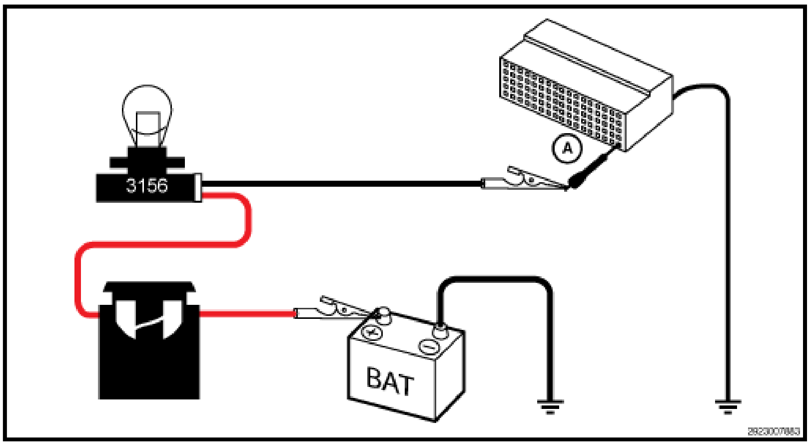
testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .

NOTE: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.

NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

Is the load test bulb illuminated and bright?

Yes

- Go To 4

No

- Repair the ground circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K399) HEATER CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **ISOLATE AND LOAD TEST THE O2 SENSOR 2/2 (K399) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
    1. The ignition must be off when performing a load test on a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
    3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.

4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at one of the component harness connectors (B).
5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

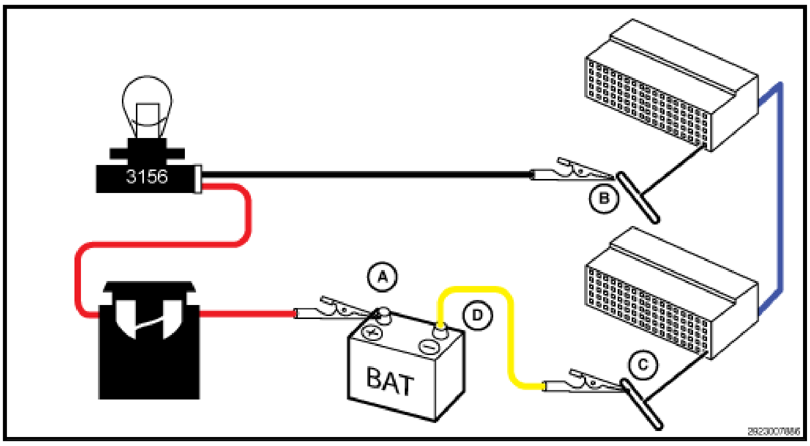
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

Is the load test bulb illuminated and bright?

Yes

- Go To 6

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE O2 SENSOR 2/2 HEATER CONTROL DRIVER FOR PROPER OPERATION**
   1. Turn the ignition off.
   2. Connect the PCM C2 harness connector.
   3. Turn the ignition on.
   4. With the scan tool, actuate the O2 Sensor 2/2 control to the maximum allowable percentage.
   5. Using a 12-volt test light connected to ground, check the O2 Sensor 2/2 (K399) Heater Control circuit at the O2 Sensor 2/2 harness connector.

   NOTE: **The test light should be illuminated. The brightness will be dependant on the actuation percentage selected.**

   6. With the scan tool, actuate the O2 Sensor 2/2 control to the OFF (0%) position.

   NOTE: **The test light should not be illuminated.**

Does the test light illuminate with the actuator ON and not illuminated with the actuator OFF (0%)?

Yes

- Replace the O2 Sensor 2/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 7

7. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0069-MANIFOLD PRESSURE/BAROMETRIC PRESSURE CORRELATION

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Ignition key is on.
- No Manifold Absolute Pressure Sensor (MAP) or Barometric Pressure Sensor (BARO) DTCs are present.
- Engine rollback protection is not active.

SET CONDITION

- Barometric pressure is greater than Manifold Absolute Pressure (plus a calibrated offset).

DEFAULT ACTION

- MIL will illuminate.
- ETC Lamp will illuminate.
- Engine speed is limited.
- Engine torque is limited.
- Transmission torque requests are disabled.

POSSIBLE CAUSES

Possible Causes
INTAKE OR EXHAUST SYSTEM RESTRICTION
MAP SENSOR
BAROMETRIC SENSOR INTERNAL TO THE POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

       Are there any Crank Sensor, Cam Sensor, or sensor supply DTCs active or pending?

       Yes

       - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 3
3. **CHECK FOR INTAKE AND EXHAUST RESTRICTIONS**
    1. Check for an air intake system restriction and exhaust system restriction.

       Were any problems found?

       Yes

       - Repair the Intake or Exhaust System restriction.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 4
4. **CHECK FOR MAP AND BARO DTCS**
    1. Refer to the recorded DTCs.

       Are there any MAP sensor or BARO sensor DTCs active or pending?

       Yes

       - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 5
5. **CHECK THE MAP SENSOR OPERATION**
    1. Perform the CHECKING THE MAP SENSOR OPERATION procedure. Refer to the appropriate information.

       Were any problems found?

       Yes

       - Repair the MAP Sensor problem.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK RELATED HARNESS CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    5. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. With the scan tool, erase DTCs.
    9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    10. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Repair the poor connections.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0071-AMBIENT AIR TEMPERATURE SENSOR PERFORMANCE

For a complete A/C CONTROL SYSTEM wiring diagram, **refer to the appropriate wiring information** .

KNOWN VEHICLE ISSUES

Listed below are vehicles that have system issues that may cause an incorrect DTC to set which may lead to misdiagnosing the system.

1. **Heavy Duty Trucks** - Trucks that are equipped with a Drivers Door Module (DDM) may set the U110E-LOST AMBIENT TEMPERATURE MESSAGE fault when there is an open in the circuitry instead of the P0073-AAT SENSOR CIRCUIT HIGH fault. When diagnosing one of these vehicles with the U110E present, always diagnose the entire circuitry and sensor first.
2. **2018 - 2019 JL** - A short to ground in the AAT Sensor Signal will set the P0073-AAT SENSOR CIRCUIT HIGH DTC instead of the P0072-AAT SENSOR CIRCUIT LOW DTC.
3. **2019 KL** - May set the U110E-LOST AMBIENT TEMPERATURE MESSAGE fault when there is an open in the circuitry instead of the P0073-AAT SENSOR CIRCUIT HIGH fault. When diagnosing one of these vehicles with the U110E present, always diagnose the entire circuitry and sensor first.

DESCRIPTION AND OPERATION - AMBIENT AIR TEMP SENSOR

The AAT Sensor is typically located in the front of the vehicle near the grill. On some vehicles the AAT Sensor is located in the drivers side mirror housing. The sensor is normally hard-wired to the Body Control Module (BCM) or Totally Integrated Power Module (TIPM) depending on vehicle architecture. On vehicles that have the sensor mounted in the mirror, it may be hard-wired to the Drivers Door Module (DDM), if equipped. Refer to the wiring information for the specific vehicle being diagnosed to determine which module to test at. The analog AAT Sensor signal is converted to a digital signal and broadcast over the vehicle Bus. If hard-wired to the DDM, it is bussed to the BCM/TIPM. The BCM/TIPM broadcasts the AAT Sensor signal over the Can C Bus. The Powertrain Control Module (PCM) acquires the AAT Sensor signal from the Can C Bus.

NOTE: **While circuit high and low faults are monitored by both the PCM and BCM, only the PCM performs a rationality diagnostic of the AAT Sensor signal.**

The AAT Sensor rationality diagnostic runs on a cold start after a cold soak condition was present on the previous key off cycle. Following a start to run delay time, the PCM typically compares the signals from the AAT, Engine Coolant Temperature (ECT), and Intake Air Temperature (IAT) Sensors. If the ECT and IAT Sensors agree and the AAT Sensor does not agree, the AAT Sensor signal is declared as irrational. If declared irrational a second comparison will be done after a short drive cycle.

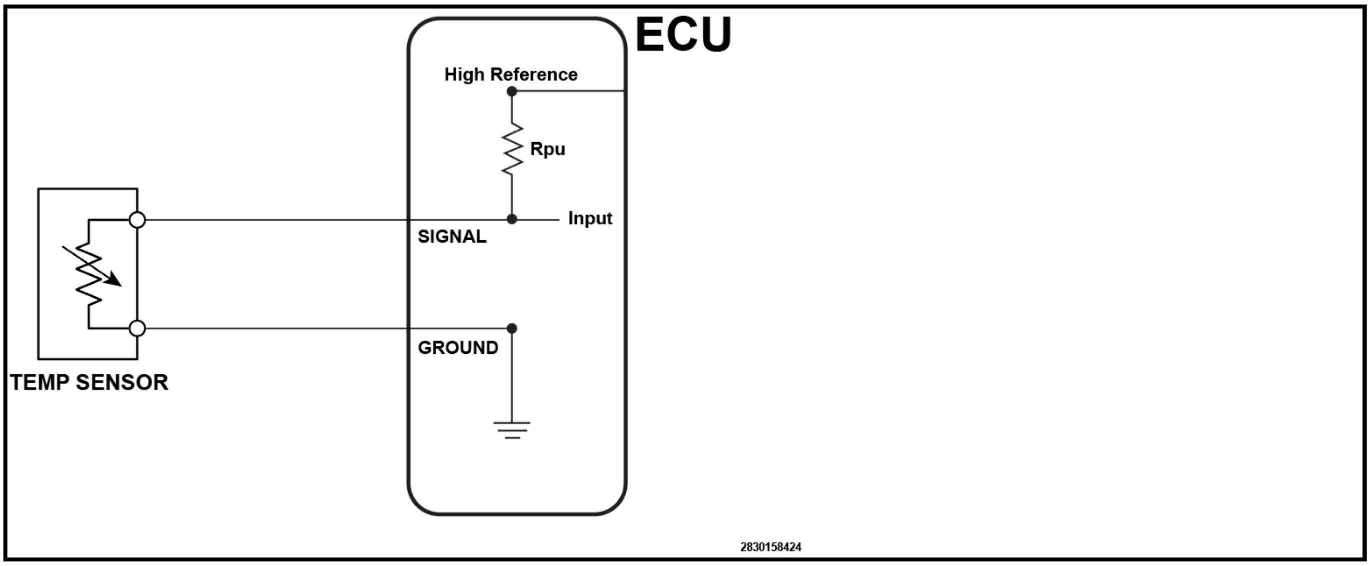
NOTE: **If a repair is performed to the AAT Sensor wiring, the sensor is replaced, or the BCM connector is disconnected during testing to correct an active DTC, the vehicle must be driven for a minimum of 5 minutes above 15 mph to update the AAT temp signal before the DTC will go stored and can be erased.**

COMPONENT FUNCTIONAL DESCRIPTION - TWO WIRE TEMP SENSOR

GENERAL OPERATION: Temperature sensors are typically a variable resistor that functions as a normal two wire, 5.0 volt sensor. An Electronic Control Unit (ECU) supplies the Temp Sensor with a 5.0 volt reference signal and a filtered ground (return) circuit. The pull up resistor (Rpu) inside the ECU is a fixed resistance. The resistance in the sensor will change in relation to temperature. The resistors are configured in a simple series circuit with the ECU internally monitoring the voltage on the signal circuit, which is converted into a digital temperature reading. As the resistance of the component increases, the voltage on the signal circuit will also increase. The increased voltage on the signal circuit can be interpreted by the ECU as the temperature increasing or decreasing depending on the temp sensor and ECU software design.

- **Circuit Fault Diagnostics:** On a normally functioning sensor with no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts would set a circuit high/open fault. A voltage below approximately 0.10 volts will set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.

- **Performance Fault Diagnostics:** Since added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault, the module will check the signal for a plausible reading in some cases. This can be done using different methods. One common way is by comparing the sensor reading to other temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (I.E. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.



ANALOG TO DIGITAL SIGNAL DESCRIPTION

Electronic Control Modules read analog signal voltages and convert them to digital counts. Each count is an equal percentage of the voltage. This can be seen when viewing the voltages of some sensors or switches on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts on most sensors to a battery voltage reference on switches.

- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals have a high resolution (Ex. a sensor signal may be divided into 4096 counts, or 5.0 volts divided by 4096). This allows the module to read small changes over a wide range in a variable resistance sensor signal used for a temperature, pressure, or position sensors.
- Switches will typically have a low resolution since they are usually only reporting a few switch states (Ex. a switch may typically be divided into only 15-20 counts, or Battery voltage divided by 15). The highest and lowest one or two counts will be used for detecting opens or shorts if the switch signal is being rationalized. The remaining counts are divided up between the states being detected.

TECHNICAL DATA - AMBIENT AIR TEMP SENSOR

Use the specification table below to check the Ambient Temperature Sensor. The values in the table show the approximate resistance values for the temperatures given. The actual resistance can vary +/- 10% form the values in the table. Typically, if the sensor is faulty the resistance value will be noticeably different from the specification in the table.

AMBIENT AIR TEMP SENSOR - TEMPERATURE TO RESISTANCE CHART			
Ambient Temp - Celsius	**Ambient Temp - Fahrenheit**	**Sensor Resistance**	**B**
-40B°C	-40B°F	345.26 kOhms	Lowest possible temperature reading
-10B°C	14B°F	53.38 kOhms	Logical temperature values
-5B°C	23B°F	40.89 kOhms	
0B°C	32B°F	31.56 kOhms	
5B°C	41B°F	24.55 kOhms	

AMBIENT AIR TEMP SENSOR - TEMPERATURE TO RESISTANCE CHART			
Ambient Temp - Celsius	**Ambient Temp - Fahrenheit**	**Sensor Resistance**	**B**
10B°C	50B°F	19.24 kOhms	
15B°C	59B°F	15.22 kOhms	
20B°C	68B°F	12.13 kOhms	
25B°C	77B°F	9720 Ohms	
30B°C	86B°F	7780 Ohms	
35B°C	95B°F	6370 Ohms	
40B°C	104B°F	5200 Ohms	
150B°C	302B°F	181 Ohms	Highest possible temperature reading

ENABLING CONDITIONS AND POSSIBLE CAUSES - AMBIENT AIR TEMP SENSOR

MONITORING CONDITIONS
Circuit Low/High Faults - With the ignition on, battery voltage above a calibrated threshold. **Performance Fault** - With the ignition on after an eight hour cold soak on the previous engine off cycle. Ambient Air, Intake Air, and Engine Coolant Temperature values are above -64B°C (-83B°F).

FAULT SETTING CRITERIA
Circuit Low Fault - The sensor signal voltage is below a calibrated threshold. The threshold is typically in the 0.1 volt range. **Circuit High Fault** - The sensor signal voltage is above a calibrated threshold. The threshold is typically in the 4.9 volt range. **Performance Fault** - The sensor signal voltage is irrational - typically not within 10B°C - 15B°C (18B°F - 27B°F) of the other engine temp sensors.

POSSIBLE CAUSES
TEMP SENSOR HARNESS CONNECTOR DAMAGED OR NOT CONNECTED COMPLETELY (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH FAULT)
TEMP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR RETURN CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
FAULTY TEMP SENSOR (OPEN, SHORTED OR DRIFTED OUT OF RANGE)
FAULTY ELECTRONIC CONTROL UNIT (ECU)

DIAGNOSTIC OVERVIEW

TEMP SENSOR ECU DIAGNOSTICS:

- **Circuit Fault Diagnostics:** With a normally functioning sensor that has no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts will typically set a circuit high/open fault. A voltage below approximately 0.10 volts will typically set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.
- **Performance Fault Diagnostics:** Added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault. The module will check the signal for a plausible reading in most cases. This can be done using different methods. One common way is by comparing the sensor reading to other

temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (Ex. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.

PRELIMINARY DIAGNOSTIC CHECKS

1. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the ECU. Low Battery voltage can cause a DTC.
3. Circuit faults should typically be diagnosed before rationality/performance faults.
4. Check the component harness connector(s) for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the component harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.
2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connections issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

Intermittent testing for a circuit low/high fault with the Mopar Scope:

1. Back probe and connect the scope lead to the temp sensor signal circuit.
2. Monitor the circuit voltage while wiggle testing the wiring harness.

3. If you are not able to monitor the scope signal voltage during wiggle testing, set up a trigger to catch an intermittent condition. Set the trigger for voltage above 4.9 volts for an intermittent circuit high fault or below 0.1 volts for a circuit low fault.

DIAGNOSTIC TEST - TWO WIRE TEMP SENSOR

NOTE: **If a repair is performed to the AAT Sensor wiring, the sensor is replaced, or the BCM connector is disconnected during testing to correct an active DTC, the vehicle must be driven for a minimum of 5 minutes above 15 mph to update the AAT temp signal before the DTC will go stored and can be erased.**

NOTE: **The AAT Sensor is an individually serviceable component. If the measured resistance from the AAT Sensor does not meet the values from the Technical Data information, then only the sensor should be replaced and not the entire mirror assembly.**

NOTE: **There are multiple test methods listed below. The first two tests are a complete system diagnostic of the wiring and sensor. The remaining tests are broken up by the failure modes. There can be advantages to using each method. All of the methods do not need to be performed. Pick the best test method based on accessibility, ease of testing, availability of test equipment. It is a good practice to perform a complete check of the wiring in case of calibration issues. Failure to perform a complete check of the wiring may lead to unnecessary replacement of the component or ECU. In some cases it may be beneficial to use parts of each method to test for different failure modes.**

COMPLETE CIRCUIT DIAGNOSTICS USING THE ELECTRICAL TEST LEAD KIT:

1. Check the ECU, signal and sensor ground circuits together to determine if the temp sensor is faulty. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the temp signal and sensor ground circuits at the temp sensor harness connector. Move the switch on the Electrical Test Lead Kit between the open and closed positions while monitoring the scan tool. If monitoring for faults, the circuit high fault should set when switched to the open position and the circuit low fault should set when switched to the closed position. If the sensor voltage is available on the scan tool, monitor the voltage readings. The voltage should be 5.0 volts when switched to the open position and 0.0 volts when switched to the closed position. Move the switch to adjust and use the tool to vary the resistance while monitoring the ECU signal voltage on the scan tool. **Pick the result from a, b, or c below that best matches the results.**

1. **If the faults set as described and the signal voltage is 5.0 volts and 0.0 volts** - the ECU and temp sensor circuits are testing good. The temp sensor is most likely faulty or has a poor connection at the harness connector. Check the temp sensor harness connector for pushed out, spread, corroded or dirty terminals before condemning the sensor. The internal resistance of the sensor can be measured and compared to the table (if available) to verify a faulty sensor.
2. **If the signal voltage is stuck low or only the circuit low fault sets** - the most likely cause is the temp sensor signal circuit shorted to chassis ground or the temp sensor ground circuit. Check the temp sensor signal circuit for a short to ground, or to the temp sensor ground circuit. If the signal circuit is not shorted, use the wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals before condemning an ECU. If no issues are found, the ECU is most likely faulty.
3. **If the signal voltage is stuck high or only the circuit high fault sets** - the most likely cause is an open or very high resistance in the temp sensor signal or temp sensor ground circuit. **Continue to step d.**
4. **If the signal reading on the scan tool shows voltage present when switched to closed** - remove the test lead from the sensor ground circuit and connect it to a good chassis ground while observing the voltage on the scan tool. If the voltage drops to 0.0 volts the resistance is in the temp sensor ground circuit. If the voltage is still present the resistance is in the temp sensor signal circuit. Check the appropriate circuit for high resistance. Typically, it should be less than 3.0 Ohms. If the circuits check good, **continue to step e.**
5. **If the circuits are checked and do not have excessive resistance** - use the wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the ECU. If no issues are found, replace the ECU in accordance with the service information.

COMPLETE CIRCUIT DIAGNOSTICS USING CONVENTIONAL VOLTAGE TESTING WITH A DVOM:

1. Verify the temp sensor and ECU harness connectors are connected and locked properly.
2. Turn the ignition on. Back probe and measure the voltage on the temp sensor signal circuit at the Fuel Pump harness connector. Pick the result below that best matches the voltage reading.
   1. **If the signal voltage is reading between 0.1 and 4.9 volts** - the temp sensor signal is most likely giving a legitimate reading. If the circuit fault is active and the voltage reading on the scan tool does not match the DVOM voltage reading, the ECU is likely faulty.
   2. **If the signal measures a constant 0.0 volts** - this indicates that the temp sensor signal circuit is shorted to ground or has an open between the ECU and temp sensor. If the circuit high fault is set, the most likely failure is an open in the temp sensor signal circuit. If the circuit low fault is set, the most likely failure is a short to ground in the temp sensor signal circuit or possibly a faulty sensor (disconnecting the temp sensor harness connector and checking for the circuit high fault to become active would indicate that the temp sensor is most likely faulty). **Continue to step 3.**
   3. **If the signal reading has a constant voltage above 6.0 volts** - this would indicate that the signal circuit is shorted to another voltage supply.
   4. **If the signal reading has a constant 5.0 volts** - this indicates an open further downstream in the circuitry. Most likely the temp sensor or the temp sensor ground circuit. **Continue to step 4.**
3. Disconnect the temp sensor and ECU harness connectors and check the temp sensor signal circuit for high resistance and short to ground. If the signal circuit checks good, check all connectors in the system for pushed out, spread, corroded or dirty terminals before condemning a ECU. If all of the connectors check good, replace the ECU in accordance with the service information.
4. To check the temp sensor, move the test lead over and back probe the temp sensor ground circuit at the temp sensor harness connector.

TYPICAL CIRCUIT LOW DIAGNOSTICS:

1. To quickly eliminate the temp sensor as a possible cause with an **active** circuit low fault, disconnect the temp sensor harness connector while monitoring for the circuit high fault to become active on the scan

tool.

1. If the circuit high fault becomes active when the sensor is disconnected, the temp sensor is most likely faulty.
2. If the circuit high fault does not become active, **continue to step 2.**

2. Disconnect the ECU harness connector to isolate the circuit. Check the temp signal circuit for continuity to both chassis ground and the sensor ground circuit.
   1. If there is continuity to either, repair the signal circuit for a short to ground or the sensor ground circuit.
   2. If the signal circuit is not shorted, replace the ECU in accordance with the service information.

TYPICAL CIRCUIT HIGH DIAGNOSTICS:

1. Disconnect the temp sensor harness connector and measure the temp sensor signal circuit voltage with the ignition on. The signal circuit voltage should be between 4.9 and 5.6 volts.
   1. If battery voltage is present, repair the sensor signal circuit for a short to another voltage supply circuit.
   2. If the voltage is correct, **continue to step 2.** .
2. With an active fault, monitor the scan tool and connect a jumper across the terminals with the ignition on. Typically, the temp sensor signal voltage should change to 0 volts on the scan tool with the jumper in place. If the voltage data read is not available, check for the circuit low fault to set with the jumper in place. If either result occurs, the temp sensor is faulty.
   1. If either result occurs, the temp sensor is faulty.
   2. If the voltage does not change to 0 volts or the circuit low fault is not present with the jumper in place, **continue to step 3.** .
3. Check the resistance of the temp sensor signal circuit and temp sensor ground circuit. Typically the circuit resistance should be less than 5.0 Ohms.
   1. If there is an open or high resistance in either circuit, repair the circuit.
   2. If the temp sensor signal and ground circuits test good, and the voltage is still reading high or only the circuit high fault is present, use the wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning ECU. If no issues are found, replace the ECU in accordance with the service information.

TYPICAL PERFORMANCE/RATIONALITY DIAGNOSTICS:

NOTE: **Temp sensor performance faults typically set due to resistance in one of the circuits or a sensor that is stuck or drifted out of range. The (special tool #2064100080, Kit, Electrical Test Lead) can be used with the scan tool to test the wiring and controller.**

1. Disconnect the temp sensor harness connector and connect the Electrical Test Kit leads to the temp sensor harness connector.
2. Move the switch on the tool to open. The signal should read 5.0 volts and a circuit high DTC should be active or pending on the scan tool.
3. Next flip the switch to the closed position. The signal should read 0 volts and a circuit low fault should be active or pending on the scan tool. If the scan tool reads as described in steps 2 and 3, it would indicate the wiring and ECU are good and the sensor is likely faulty. If there is voltage present between 0 and 5.0 volts with the test tool in the closed position it would indicate there is likely resistance in one of the circuits. **Continue to step a.**
   1. To determine which circuit has resistance, remove the test lead connected to the temp sensor ground circuit and connect it to a good chassis ground.
      - If the signal changes to 0 volts it would indicate the temp sensor ground has resistance. **Continue to step b.**

- If there is still voltage present it would indicate the temp sensor signal has resistance. **Continue to step b.**

2. Confirm the suspect circuit issue by isolating the suspect circuit and measuring the resistance of the circuit between the sensor and ECU harness connectors. If no resistance is measured, carefully check all connectors in the path of the circuit for spread or dirty/corroded terminals. If the circuits check good (no resistance), verify whether the issue is with the temp sensor or ECU. **Continue to step 4 or 5.**

4. **If a temp table is available** , the sensor and ECU can be verified in one of the following ways.
    1. Move the switch to adjust and connect an Ohmmeter to the test leads and dial the tool to a resistance value in the table. Connect both leads to the temp sensor harness connector with the ignition on and monitor the data in the scan tool for the proper reading. Use the tool to vary the resistance while monitoring the temp sensor signal temperature/voltage on the scan tool. If the reading matches the table, the temp sensor is likely faulty.
    2. If the temp sensor actual temperature can be acquired or reasonably estimated, measure the resistance across the terminals of the temp sensor and compare to the value in the table. If the resistance of the sensor is not in range of the table, the temp sensor is likely faulty.
5. **If a temp table is not available** for the sensor being tested, connect the Electrical Test Kit leads to the harness connector and flip the switch to adjust. With the ignition on, monitor the scan tool data and slowly adjust the resistance in the circuit. The temperature/voltage value should change with the resistance change. If the value changes as the resistance is varied it would indicate that the temp sensor is likely faulty.

VERIFYING AN ECU FAILURE: An ECU that is faulty and not able to properly read the signal can usually be determined when opening and shorting the circuits and monitoring the signal voltage and fault codes. If the expected voltage reads or DTCs do not occur when opening and jumping the connector, and the circuits are not shorted or open, it would indicate a faulty ECU. Before condemning and ECU, **always** carefully check all connectors in the path of the circuit for water intrusion, spread, pushed out, burnt or corroded terminals.

P0072-AMBIENT AIR TEMPERATURE SENSOR CIRCUIT LOW

For a complete A/C CONTROL SYSTEM wiring diagram, **refer to the appropriate wiring information** .

KNOWN VEHICLE ISSUES

Listed below are vehicles that have system issues that may cause an incorrect DTC to set which may lead to misdiagnosing the system.

1. **Heavy Duty Trucks** - Trucks that are equipped with a Drivers Door Module (DDM) may set the U110E-LOST AMBIENT TEMPERATURE MESSAGE fault when there is an open in the circuitry instead of the P0073-AAT SENSOR CIRCUIT HIGH fault. When diagnosing one of these vehicles with the U110E present, always diagnose the entire circuitry and sensor first.
2. **2018 - 2019 JL** - A short to ground in the AAT Sensor Signal will set the P0073-AAT SENSOR CIRCUIT HIGH DTC instead of the P0072-AAT SENSOR CIRCUIT LOW DTC.
3. **2019 KL** - May set the U110E-LOST AMBIENT TEMPERATURE MESSAGE fault when there is an open in the circuitry instead of the P0073-AAT SENSOR CIRCUIT HIGH fault. When diagnosing one of these vehicles with the U110E present, always diagnose the entire circuitry and sensor first.

DESCRIPTION AND OPERATION - AMBIENT AIR TEMP SENSOR

The AAT Sensor is typically located in the front of the vehicle near the grill. On some vehicles the AAT Sensor is located in the drivers side mirror housing. The sensor is normally hard-wired to the Body Control Module (BCM) or Totally Integrated Power Module (TIPM) depending on vehicle architecture. On vehicles that have the sensor mounted in the mirror, it may be hard-wired to the Drivers Door Module (DDM), if equipped. Refer to the wiring information for the specific vehicle being diagnosed to determine which module to test at. The analog AAT Sensor signal is converted to a digital signal and broadcast over the vehicle Bus. If hard-wired to the DDM, it is bussed to the BCM/TIPM. The BCM/TIPM broadcasts the AAT Sensor signal over the Can C Bus. The Powertrain Control Module (PCM) acquires the AAT Sensor signal from the Can C Bus.

NOTE: **While circuit high and low faults are monitored by both the PCM and BCM, only the PCM performs a rationality diagnostic of the AAT Sensor signal.**

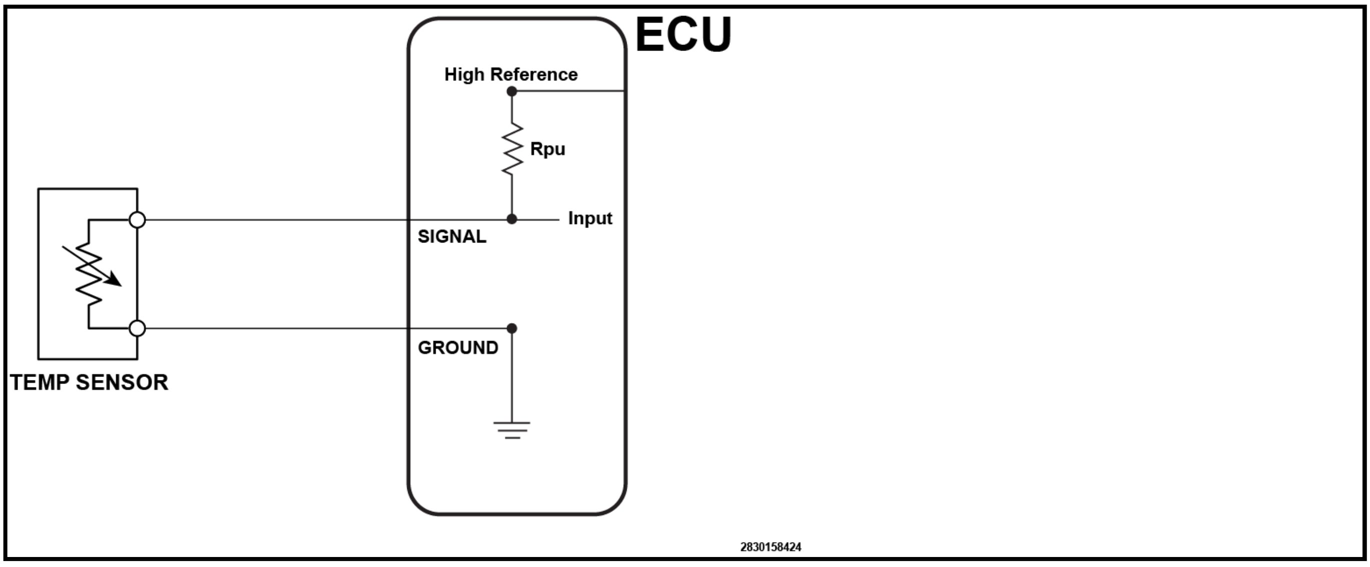
The AAT Sensor rationality diagnostic runs on a cold start after a cold soak condition was present on the previous key off cycle. Following a start to run delay time, the PCM typically compares the signals from the AAT, Engine Coolant Temperature (ECT), and Intake Air Temperature (IAT) Sensors. If the ECT and IAT Sensors agree and the AAT Sensor does not agree, the AAT Sensor signal is declared as irrational. If declared irrational a second comparison will be done after a short drive cycle.

NOTE: **If a repair is performed to the AAT Sensor wiring, the sensor is replaced, or the BCM connector is disconnected during testing to correct an active DTC, the vehicle must be driven for a minimum of 5 minutes above 15 mph to update the AAT temp signal before the DTC will go stored and can be erased.**

COMPONENT FUNCTIONAL DESCRIPTION - TWO WIRE TEMP SENSOR

GENERAL OPERATION: Temperature sensors are typically a variable resistor that functions as a normal two wire, 5.0 volt sensor. An Electronic Control Unit (ECU) supplies the Temp Sensor with a 5.0 volt reference signal and a filtered ground (return) circuit. The pull up resistor (Rpu) inside the ECU is a fixed resistance. The resistance in the sensor will change in relation to temperature. The resistors are configured in a simple series circuit with the ECU internally monitoring the voltage on the signal circuit, which is converted into a digital temperature reading. As the resistance of the component increases, the voltage on the signal circuit will also increase. The increased voltage on the signal circuit can be interpreted by the ECU as the temperature increasing or decreasing depending on the temp sensor and ECU software design.

- **Circuit Fault Diagnostics:** On a normally functioning sensor with no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts would set a circuit high/open fault. A voltage below approximately 0.10 volts will set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.
- **Performance Fault Diagnostics:** Since added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault, the module will check the signal for a plausible reading in some cases. This can be done using different methods. One common way is by comparing the sensor reading to other temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (I.E. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.



ANALOG TO DIGITAL SIGNAL DESCRIPTION

Electronic Control Modules read analog signal voltages and convert them to digital counts. Each count is an equal percentage of the voltage. This can be seen when viewing the voltages of some sensors or switches on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts on most sensors to a battery voltage reference on switches.

- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals have a high resolution (Ex. a sensor signal may be divided into 4096 counts, or 5.0 volts divided by 4096). This allows the module to read small changes over a wide range in a variable resistance sensor signal used for a temperature, pressure, or position sensors.
- Switches will typically have a low resolution since they are usually only reporting a few switch states (Ex. a switch may typically be divided into only 15-20 counts, or Battery voltage divided by 15). The highest and lowest one or two counts will be used for detecting opens or shorts if the switch signal is being rationalized. The remaining counts are divided up between the states being detected.

TECHNICAL DATA - AMBIENT AIR TEMP SENSOR

Use the specification table below to check the Ambient Temperature Sensor. The values in the table show the approximate resistance values for the temperatures given. The actual resistance can vary +/- 10% form the values in the table. Typically, if the sensor is faulty the resistance value will be noticeably different from the specification in the table.

AMBIENT AIR TEMP SENSOR - TEMPERATURE TO RESISTANCE CHART			
Ambient Temp - Celsius	**Ambient Temp - Fahrenheit**	**Sensor Resistance**	**B**
-40B°C	-40B°F	345.26 kOhms	Lowest possible temperature reading
-10B°C	14B°F	53.38 kOhms	Logical temperature values
-5B°C	23B°F	40.89 kOhms	
0B°C	32B°F	31.56 kOhms	
5B°C	41B°F	24.55 kOhms	
10B°C	50B°F	19.24 kOhms	
15B°C	59B°F	15.22 kOhms	
20B°C	68B°F	12.13 kOhms	
25B°C	77B°F	9720 Ohms	
30B°C	86B°F	7780 Ohms	
35B°C	95B°F	6370 Ohms	
40B°C	104B°F	5200 Ohms	
150B°C	302B°F	181 Ohms	Highest possible temperature reading

ENABLING CONDITIONS AND POSSIBLE CAUSES - AMBIENT AIR TEMP SENSOR

MONITORING CONDITIONS
Circuit Low/High Faults - With the ignition on, battery voltage above a calibrated threshold. **Performance Fault** - With the ignition on after an eight hour cold soak on the previous engine off cycle. Ambient Air, Intake Air, and Engine Coolant Temperature values are above -64B°C (-83B°F).

FAULT SETTING CRITERIA
Circuit Low Fault - The sensor signal voltage is below a calibrated threshold. The threshold is typically in the 0.1 volt range. **Circuit High Fault** - The sensor signal voltage is above a calibrated threshold. The threshold is typically in the 4.9 volt range. **Performance Fault** - The sensor signal voltage is irrational - typically not within 10B°C - 15B°C (18B°F - 27B°F) of the other engine temp sensors.

POSSIBLE CAUSES
TEMP SENSOR HARNESS CONNECTOR DAMAGED OR NOT CONNECTED COMPLETELY (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH FAULT)
TEMP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR RETURN CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
FAULTY TEMP SENSOR (OPEN, SHORTED OR DRIFTED OUT OF RANGE)
FAULTY ELECTRONIC CONTROL UNIT (ECU)

DIAGNOSTIC OVERVIEW

TEMP SENSOR ECU DIAGNOSTICS:

- **Circuit Fault Diagnostics:** With a normally functioning sensor that has no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts will typically set a circuit high/open fault. A voltage below approximately 0.10 volts will typically set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.
- **Performance Fault Diagnostics:** Added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault. The module will check the signal for a plausible reading in most cases. This can be done using different methods. One common way is by comparing the sensor reading to other temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (Ex. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.

PRELIMINARY DIAGNOSTIC CHECKS

1. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the ECU. Low Battery voltage can cause a DTC.
3. Circuit faults should typically be diagnosed before rationality/performance faults.
4. Check the component harness connector(s) for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the component harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not

be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.

2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connections issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

Intermittent testing for a circuit low/high fault with the Mopar Scope:

1. Back probe and connect the scope lead to the temp sensor signal circuit.
2. Monitor the circuit voltage while wiggle testing the wiring harness.
3. If you are not able to monitor the scope signal voltage during wiggle testing, set up a trigger to catch an intermittent condition. Set the trigger for voltage above 4.9 volts for an intermittent circuit high fault or below 0.1 volts for a circuit low fault.

DIAGNOSTIC TEST - TWO WIRE TEMP SENSOR

NOTE: **If a repair is performed to the AAT Sensor wiring, the sensor is replaced, or the BCM connector is disconnected during testing to correct an active DTC, the vehicle must be driven for a minimum of 5 minutes above 15 mph to update the AAT temp signal before the DTC will go stored and can be erased.**

NOTE: **The AAT Sensor is an individually serviceable component. If the measured resistance from the AAT Sensor does not meet the values from the Technical Data information, then only the sensor should be replaced and not the entire mirror assembly.**

NOTE: **There are multiple test methods listed below. The first two tests are a complete system diagnostic of the wiring and sensor. The remaining tests are broken up by the failure modes. There can be advantages to using each method. All of the methods do not need to be performed. Pick the best test method based on accessibility, ease of testing, availability of test equipment. It is a good practice to perform a complete check of the wiring in case of calibration issues. Failure to perform a complete check of the wiring may lead to unnecessary replacement of the component or ECU. In some cases it may be beneficial to use parts of each method to test for different failure modes.**

COMPLETE CIRCUIT DIAGNOSTICS USING THE ELECTRICAL TEST LEAD KIT:

1. Check the ECU, signal and sensor ground circuits together to determine if the temp sensor is faulty. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the temp signal and sensor ground

circuits at the temp sensor harness connector. Move the switch on the Electrical Test Lead Kit between the open and closed positions while monitoring the scan tool. If monitoring for faults, the circuit high fault should set when switched to the open position and the circuit low fault should set when switched to the closed position. If the sensor voltage is available on the scan tool, monitor the voltage readings. The voltage should be 5.0 volts when switched to the open position and 0.0 volts when switched to the closed position. Move the switch to adjust and use the tool to vary the resistance while monitoring the ECU signal voltage on the scan tool. **Pick the result from a, b, or c below that best matches the results.**

1. **If the faults set as described and the signal voltage is 5.0 volts and 0.0 volts** - the ECU and temp sensor circuits are testing good. The temp sensor is most likely faulty or has a poor connection at the harness connector. Check the temp sensor harness connector for pushed out, spread, corroded or dirty terminals before condemning the sensor. The internal resistance of the sensor can be measured and compared to the table (if available) to verify a faulty sensor.
2. **If the signal voltage is stuck low or only the circuit low fault sets** - the most likely cause is the temp sensor signal circuit shorted to chassis ground or the temp sensor ground circuit. Check the temp sensor signal circuit for a short to ground, or to the temp sensor ground circuit. If the signal circuit is not shorted, use the wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals before condemning an ECU. If no issues are found, the ECU is most likely faulty.
3. **If the signal voltage is stuck high or only the circuit high fault sets** - the most likely cause is an open or very high resistance in the temp sensor signal or temp sensor ground circuit. **Continue to step d.**
4. **If the signal reading on the scan tool shows voltage present when switched to closed** - remove the test lead from the sensor ground circuit and connect it to a good chassis ground while observing the voltage on the scan tool. If the voltage drops to 0.0 volts the resistance is in the temp sensor ground circuit. If the voltage is still present the resistance is in the temp sensor signal circuit. Check the appropriate circuit for high resistance. Typically, it should be less than 3.0 Ohms. If the circuits check good, **continue to step e.**
5. **If the circuits are checked and do not have excessive resistance** - use the wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the ECU. If no issues are found, replace the ECU in accordance with the service information.

COMPLETE CIRCUIT DIAGNOSTICS USING CONVENTIONAL VOLTAGE TESTING WITH A DVOM:

1. Verify the temp sensor and ECU harness connectors are connected and locked properly.

2. Turn the ignition on. Back probe and measure the voltage on the temp sensor signal circuit at the Fuel Pump harness connector. Pick the result below that best matches the voltage reading.
    1. **If the signal voltage is reading between 0.1 and 4.9 volts** - the temp sensor signal is most likely giving a legitimate reading. If the circuit fault is active and the voltage reading on the scan tool does not match the DVOM voltage reading, the ECU is likely faulty.
    2. **If the signal measures a constant 0.0 volts** - this indicates that the temp sensor signal circuit is shorted to ground or has an open between the ECU and temp sensor. If the circuit high fault is set, the most likely failure is an open in the temp sensor signal circuit. If the circuit low fault is set, the most likely failure is a short to ground in the temp sensor signal circuit or possibly a faulty sensor (disconnecting the temp sensor harness connector and checking for the circuit high fault to become active would indicate that the temp sensor is most likely faulty). **Continue to step 3.**
    3. **If the signal reading has a constant voltage above 6.0 volts** - this would indicate that the signal circuit is shorted to another voltage supply.
    4. **If the signal reading has a constant 5.0 volts** - this indicates an open further downstream in the circuitry. Most likely the temp sensor or the temp sensor ground circuit. **Continue to step 4.**
3. Disconnect the temp sensor and ECU harness connectors and check the temp sensor signal circuit for high resistance and short to ground. If the signal circuit checks good, check all connectors in the system for pushed out, spread, corroded or dirty terminals before condemning a ECU. If all of the connectors check good, replace the ECU in accordance with the service information.
4. To check the temp sensor, move the test lead over and back probe the temp sensor ground circuit at the temp sensor harness connector.

TYPICAL CIRCUIT LOW DIAGNOSTICS:

1. To quickly eliminate the temp sensor as a possible cause with an **active** circuit low fault, disconnect the temp sensor harness connector while monitoring for the circuit high fault to become active on the scan tool.
    1. If the circuit high fault becomes active when the sensor is disconnected, the temp sensor is most likely faulty.
    2. If the circuit high fault does not become active, **continue to step 2.**
2. Disconnect the ECU harness connector to isolate the circuit. Check the temp signal circuit for continuity to both chassis ground and the sensor ground circuit.
    1. If there is continuity to either, repair the signal circuit for a short to ground or the sensor ground circuit.
    2. If the signal circuit is not shorted, replace the ECU in accordance with the service information.

TYPICAL CIRCUIT HIGH DIAGNOSTICS:

1. Disconnect the temp sensor harness connector and measure the temp sensor signal circuit voltage with the ignition on. The signal circuit voltage should be between 4.9 and 5.6 volts.
    1. If battery voltage is present, repair the sensor signal circuit for a short to another voltage supply circuit.
    2. If the voltage is correct, **continue to step 2.** .
2. With an active fault, monitor the scan tool and connect a jumper across the terminals with the ignition on. Typically, the temp sensor signal voltage should change to 0 volts on the scan tool with the jumper in place. If the voltage data read is not available, check for the circuit low fault to set with the jumper in place. If either result occurs, the temp sensor is faulty.
    1. If either result occurs, the temp sensor is faulty.
    2. If the voltage does not change to 0 volts or the circuit low fault is not present with the jumper in place, **continue to step 3.** .
3. Check the resistance of the temp sensor signal circuit and temp sensor ground circuit. Typically the circuit resistance should be less than 5.0 Ohms.
    1. If there is an open or high resistance in either circuit, repair the circuit.

2. If the temp sensor signal and ground circuits test good, and the voltage is still reading high or only the circuit high fault is present, use the wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning ECU. If no issues are found, replace the ECU in accordance with the service information.

TYPICAL PERFORMANCE/RATIONALITY DIAGNOSTICS:

NOTE: Temp sensor performance faults typically set due to resistance in one of the circuits or a sensor that is stuck or drifted out of range. The (special tool #2064100080, Kit, Electrical Test Lead) can be used with the scan tool to test the wiring and controller.

1. Disconnect the temp sensor harness connector and connect the Electrical Test Kit leads to the temp sensor harness connector.
2. Move the switch on the tool to open. The signal should read 5.0 volts and a circuit high DTC should be active or pending on the scan tool.
3. Next flip the switch to the closed position. The signal should read 0 volts and a circuit low fault should be active or pending on the scan tool. If the scan tool reads as described in steps 2 and 3, it would indicate the wiring and ECU are good and the sensor is likely faulty. If there is voltage present between 0 and 5.0 volts with the test tool in the closed position it would indicate there is likely resistance in one of the circuits. **Continue to step a.**
    1. To determine which circuit has resistance, remove the test lead connected to the temp sensor ground circuit and connect it to a good chassis ground.
        - If the signal changes to 0 volts it would indicate the temp sensor ground has resistance. **Continue to step b.**
        - If there is still voltage present it would indicate the temp sensor signal has resistance. **Continue to step b.**
    2. Confirm the suspect circuit issue by isolating the suspect circuit and measuring the resistance of the circuit between the sensor and ECU harness connectors. If no resistance is measured, carefully check all connectors in the path of the circuit for spread or dirty/corroded terminals. If the circuits check good (no resistance), verify whether the issue is with the temp sensor or ECU. **Continue to step 4 or 5.**
4. **If a temp table is available** , the sensor and ECU can be verified in one of the following ways.
    1. Move the switch to adjust and connect an Ohmmeter to the test leads and dial the tool to a resistance value in the table. Connect both leads to the temp sensor harness connector with the ignition on and monitor the data in the scan tool for the proper reading. Use the tool to vary the resistance while monitoring the temp sensor signal temperature/voltage on the scan tool. If the reading matches the table, the temp sensor is likely faulty.
    2. If the temp sensor actual temperature can be acquired or reasonably estimated, measure the resistance across the terminals of the temp sensor and compare to the value in the table. If the resistance of the sensor is not in range of the table, the temp sensor is likely faulty.
5. **If a temp table is not available** for the sensor being tested, connect the Electrical Test Kit leads to the harness connector and flip the switch to adjust. With the ignition on, monitor the scan tool data and slowly adjust the resistance in the circuit. The temperature/voltage value should change with the resistance change. If the value changes as the resistance is varied it would indicate that the temp sensor is likely faulty.

VERIFYING AN ECU FAILURE: An ECU that is faulty and not able to properly read the signal can usually be determined when opening and shorting the circuits and monitoring the signal voltage and fault codes. If the expected voltage reads or DTCs do not occur when opening and jumping the connector, and the circuits are not shorted or open, it would indicate a faulty ECU. Before condemning and ECU, **always** carefully check all connectors in the path of the circuit for water intrusion, spread, pushed out, burnt or corroded terminals.

P0073-AMBIENT AIR TEMPERATURE SENSOR CIRCUIT HIGH

For a complete A/C CONTROL SYSTEM wiring diagram, **refer to the appropriate wiring information** .

KNOWN VEHICLE ISSUES

Listed below are vehicles that have system issues that may cause an incorrect DTC to set which may lead to misdiagnosing the system.

1. **Heavy Duty Trucks** - Trucks that are equipped with a Drivers Door Module (DDM) may set the U110E-LOST AMBIENT TEMPERATURE MESSAGE fault when there is an open in the circuitry instead of the P0073-AAT SENSOR CIRCUIT HIGH fault. When diagnosing one of these vehicles with the U110E present, always diagnose the entire circuitry and sensor first.
2. **2018 - 2019 JL** - A short to ground in the AAT Sensor Signal will set the P0073-AAT SENSOR CIRCUIT HIGH DTC instead of the P0072-AAT SENSOR CIRCUIT LOW DTC.
3. **2019 KL** - May set the U110E-LOST AMBIENT TEMPERATURE MESSAGE fault when there is an open in the circuitry instead of the P0073-AAT SENSOR CIRCUIT HIGH fault. When diagnosing one of these vehicles with the U110E present, always diagnose the entire circuitry and sensor first.

DESCRIPTION AND OPERATION - AMBIENT AIR TEMP SENSOR

The AAT Sensor is typically located in the front of the vehicle near the grill. On some vehicles the AAT Sensor is located in the drivers side mirror housing. The sensor is normally hard-wired to the Body Control Module (BCM) or Totally Integrated Power Module (TIPM) depending on vehicle architecture. On vehicles that have the sensor mounted in the mirror, it may be hard-wired to the Drivers Door Module (DDM), if equipped. Refer to the wiring information for the specific vehicle being diagnosed to determine which module to test at. The analog AAT Sensor signal is converted to a digital signal and broadcast over the vehicle Bus. If hard-wired to the DDM, it is bussed to the BCM/TIPM. The BCM/TIPM broadcasts the AAT Sensor signal over the Can C Bus. The Powertrain Control Module (PCM) acquires the AAT Sensor signal from the Can C Bus.

NOTE:	**While circuit high and low faults are monitored by both the PCM and BCM, only the PCM performs a rationality diagnostic of the AAT Sensor signal.**

The AAT Sensor rationality diagnostic runs on a cold start after a cold soak condition was present on the previous key off cycle. Following a start to run delay time, the PCM typically compares the signals from the AAT, Engine Coolant Temperature (ECT), and Intake Air Temperature (IAT) Sensors. If the ECT and IAT Sensors agree and the AAT Sensor does not agree, the AAT Sensor signal is declared as irrational. If declared irrational a second comparison will be done after a short drive cycle.

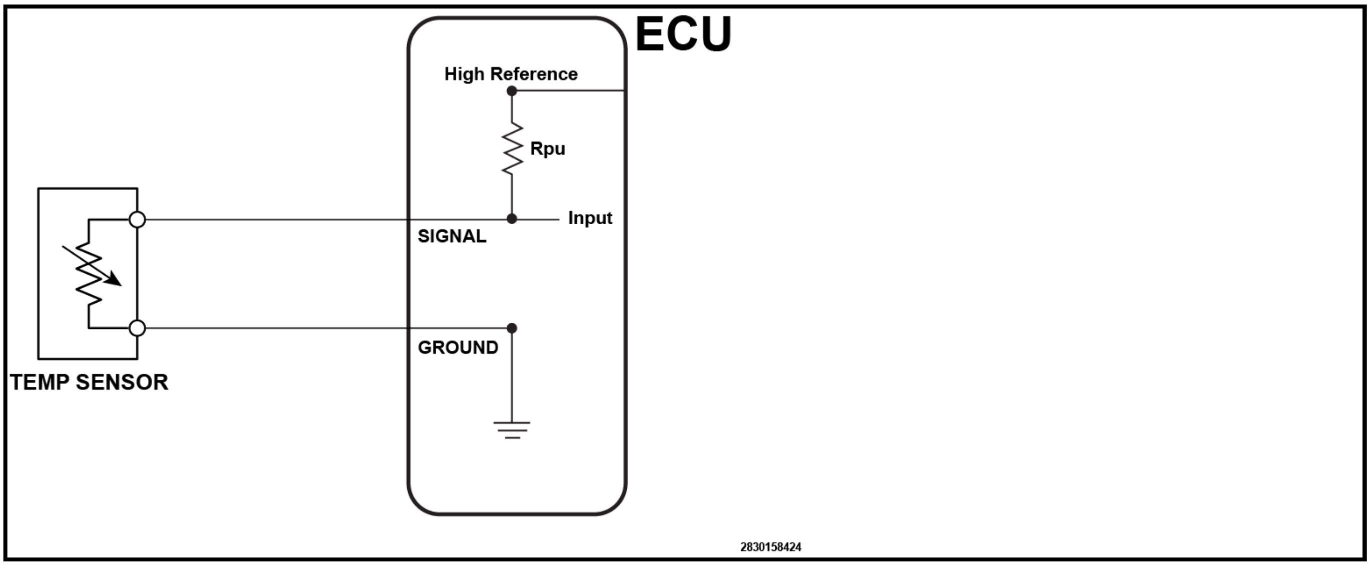
NOTE:	**If a repair is performed to the AAT Sensor wiring, the sensor is replaced, or the BCM connector is disconnected during testing to correct an active DTC, the vehicle must be driven for a minimum of 5 minutes above 15 mph to update the AAT temp signal before the DTC will go stored and can be erased.**

COMPONENT FUNCTIONAL DESCRIPTION - TWO WIRE TEMP SENSOR

GENERAL OPERATION: Temperature sensors are typically a variable resistor that functions as a normal two wire, 5.0 volt sensor. An Electronic Control Unit (ECU) supplies the Temp Sensor with a 5.0 volt reference signal and a filtered ground (return) circuit. The pull up resistor (Rpu) inside the ECU is a fixed resistance. The resistance in the sensor will change in relation to temperature. The resistors are configured in a simple series circuit with the ECU internally monitoring the voltage on the signal circuit, which is converted into a digital temperature reading. As the resistance of the component increases, the voltage on the signal circuit will also increase. The increased voltage on the signal circuit can be interpreted by the ECU as the temperature increasing or decreasing depending on the temp sensor and ECU software design.

- **Circuit Fault Diagnostics:** On a normally functioning sensor with no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts would set a circuit high/open fault. A voltage below approximately 0.10 volts will set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.

- **Performance Fault Diagnostics:** Since added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault, the module will check the signal for a plausible reading in some cases. This can be done using different methods. One common way is by comparing the sensor reading to other temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (I.E. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.



ANALOG TO DIGITAL SIGNAL DESCRIPTION

Electronic Control Modules read analog signal voltages and convert them to digital counts. Each count is an equal percentage of the voltage. This can be seen when viewing the voltages of some sensors or switches on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts on most sensors to a battery voltage reference on switches.

- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals have a high resolution (Ex. a sensor signal may be divided into 4096 counts, or 5.0 volts divided by 4096). This allows the module to read small changes over a wide range in a variable resistance sensor signal used for a temperature, pressure, or position sensors.
- Switches will typically have a low resolution since they are usually only reporting a few switch states (Ex. a switch may typically be divided into only 15-20 counts, or Battery voltage divided by 15). The highest and lowest one or two counts will be used for detecting opens or shorts if the switch signal is being rationalized. The remaining counts are divided up between the states being detected.

TECHNICAL DATA - AMBIENT AIR TEMP SENSOR

Use the specification table below to check the Ambient Temperature Sensor. The values in the table show the approximate resistance values for the temperatures given. The actual resistance can vary +/- 10% form the values in the table. Typically, if the sensor is faulty the resistance value will be noticeably different from the specification in the table.

AMBIENT AIR TEMP SENSOR - TEMPERATURE TO RESISTANCE CHART			
Ambient Temp - Celsius	**Ambient Temp - Fahrenheit**	**Sensor Resistance**	**B**
-40B°C	-40B°F	345.26 kOhms	Lowest possible temperature reading
-10B°C	14B°F	53.38 kOhms	Logical temperature values
-5B°C	23B°F	40.89 kOhms	
0B°C	32B°F	31.56 kOhms	
5B°C	41B°F	24.55 kOhms	

AMBIENT AIR TEMP SENSOR - TEMPERATURE TO RESISTANCE CHART			
Ambient Temp - Celsius	**Ambient Temp - Fahrenheit**	**Sensor Resistance**	**B**
10B°C	50B°F	19.24 kOhms	
15B°C	59B°F	15.22 kOhms	
20B°C	68B°F	12.13 kOhms	
25B°C	77B°F	9720 Ohms	
30B°C	86B°F	7780 Ohms	
35B°C	95B°F	6370 Ohms	
40B°C	104B°F	5200 Ohms	
150B°C	302B°F	181 Ohms	Highest possible temperature reading

ENABLING CONDITIONS AND POSSIBLE CAUSES - AMBIENT AIR TEMP SENSOR

MONITORING CONDITIONS
Circuit Low/High Faults - With the ignition on, battery voltage above a calibrated threshold. **Performance Fault** - With the ignition on after an eight hour cold soak on the previous engine off cycle. Ambient Air, Intake Air, and Engine Coolant Temperature values are above -64B°C (-83B°F).

FAULT SETTING CRITERIA
Circuit Low Fault - The sensor signal voltage is below a calibrated threshold. The threshold is typically in the 0.1 volt range. **Circuit High Fault** - The sensor signal voltage is above a calibrated threshold. The threshold is typically in the 4.9 volt range. **Performance Fault** - The sensor signal voltage is irrational - typically not within 10B°C - 15B°C (18B°F - 27B°F) of the other engine temp sensors.

POSSIBLE CAUSES
TEMP SENSOR HARNESS CONNECTOR DAMAGED OR NOT CONNECTED COMPLETELY (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH FAULT)
TEMP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR RETURN CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
FAULTY TEMP SENSOR (OPEN, SHORTED OR DRIFTED OUT OF RANGE)
FAULTY ELECTRONIC CONTROL UNIT (ECU)

DIAGNOSTIC OVERVIEW

TEMP SENSOR ECU DIAGNOSTICS:

- **Circuit Fault Diagnostics:** With a normally functioning sensor that has no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts will typically set a circuit high/open fault. A voltage below approximately 0.10 volts will typically set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.
- **Performance Fault Diagnostics:** Added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault. The module will check the signal for a plausible reading in most cases. This can be done using different methods. One common way is by comparing the sensor reading to other

temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (Ex. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.

PRELIMINARY DIAGNOSTIC CHECKS

1. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the ECU. Low Battery voltage can cause a DTC.
3. Circuit faults should typically be diagnosed before rationality/performance faults.
4. Check the component harness connector(s) for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the component harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.
2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connections issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

Intermittent testing for a circuit low/high fault with the Mopar Scope:

1. Back probe and connect the scope lead to the temp sensor signal circuit.
2. Monitor the circuit voltage while wiggle testing the wiring harness.

3. If you are not able to monitor the scope signal voltage during wiggle testing, set up a trigger to catch an intermittent condition. Set the trigger for voltage above 4.9 volts for an intermittent circuit high fault or below 0.1 volts for a circuit low fault.

DIAGNOSTIC TEST - TWO WIRE TEMP SENSOR

NOTE: **If a repair is performed to the AAT Sensor wiring, the sensor is replaced, or the BCM connector is disconnected during testing to correct an active DTC, the vehicle must be driven for a minimum of 5 minutes above 15 mph to update the AAT temp signal before the DTC will go stored and can be erased.**

NOTE: **The AAT Sensor is an individually serviceable component. If the measured resistance from the AAT Sensor does not meet the values from the Technical Data information, then only the sensor should be replaced and not the entire mirror assembly.**

NOTE: **There are multiple test methods listed below. The first two tests are a complete system diagnostic of the wiring and sensor. The remaining tests are broken up by the failure modes. There can be advantages to using each method. All of the methods do not need to be performed. Pick the best test method based on accessibility, ease of testing, availability of test equipment. It is a good practice to perform a complete check of the wiring in case of calibration issues. Failure to perform a complete check of the wiring may lead to unnecessary replacement of the component or ECU. In some cases it may be beneficial to use parts of each method to test for different failure modes.**

COMPLETE CIRCUIT DIAGNOSTICS USING THE ELECTRICAL TEST LEAD KIT:

1. Check the ECU, signal and sensor ground circuits together to determine if the temp sensor is faulty. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the temp signal and sensor ground circuits at the temp sensor harness connector. Move the switch on the Electrical Test Lead Kit between the open and closed positions while monitoring the scan tool. If monitoring for faults, the circuit high fault should set when switched to the open position and the circuit low fault should set when switched to the closed position. If the sensor voltage is available on the scan tool, monitor the voltage readings. The voltage should be 5.0 volts when switched to the open position and 0.0 volts when switched to the closed position. Move the switch to adjust and use the tool to vary the resistance while monitoring the ECU signal voltage on the scan tool. **Pick the result from a, b, or c below that best matches the results.**

1. **If the faults set as described and the signal voltage is 5.0 volts and 0.0 volts** - the ECU and temp sensor circuits are testing good. The temp sensor is most likely faulty or has a poor connection at the harness connector. Check the temp sensor harness connector for pushed out, spread, corroded or dirty terminals before condemning the sensor. The internal resistance of the sensor can be measured and compared to the table (if available) to verify a faulty sensor.
2. **If the signal voltage is stuck low or only the circuit low fault sets** - the most likely cause is the temp sensor signal circuit shorted to chassis ground or the temp sensor ground circuit. Check the temp sensor signal circuit for a short to ground, or to the temp sensor ground circuit. If the signal circuit is not shorted, use the wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals before condemning an ECU. If no issues are found, the ECU is most likely faulty.
3. **If the signal voltage is stuck high or only the circuit high fault sets** - the most likely cause is an open or very high resistance in the temp sensor signal or temp sensor ground circuit. **Continue to step d.**
4. **If the signal reading on the scan tool shows voltage present when switched to closed** - remove the test lead from the sensor ground circuit and connect it to a good chassis ground while observing the voltage on the scan tool. If the voltage drops to 0.0 volts the resistance is in the temp sensor ground circuit. If the voltage is still present the resistance is in the temp sensor signal circuit. Check the appropriate circuit for high resistance. Typically, it should be less than 3.0 Ohms. If the circuits check good, **continue to step e.**
5. **If the circuits are checked and do not have excessive resistance** - use the wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the ECU. If no issues are found, replace the ECU in accordance with the service information.

COMPLETE CIRCUIT DIAGNOSTICS USING CONVENTIONAL VOLTAGE TESTING WITH A DVOM:

1. Verify the temp sensor and ECU harness connectors are connected and locked properly.
2. Turn the ignition on. Back probe and measure the voltage on the temp sensor signal circuit at the Fuel Pump harness connector. Pick the result below that best matches the voltage reading.
    1. **If the signal voltage is reading between 0.1 and 4.9 volts** - the temp sensor signal is most likely giving a legitimate reading. If the circuit fault is active and the voltage reading on the scan tool does not match the DVOM voltage reading, the ECU is likely faulty.
    2. **If the signal measures a constant 0.0 volts** - this indicates that the temp sensor signal circuit is shorted to ground or has an open between the ECU and temp sensor. If the circuit high fault is set, the most likely failure is an open in the temp sensor signal circuit. If the circuit low fault is set, the most likely failure is a short to ground in the temp sensor signal circuit or possibly a faulty sensor (disconnecting the temp sensor harness connector and checking for the circuit high fault to become active would indicate that the temp sensor is most likely faulty). **Continue to step 3.**
    3. **If the signal reading has a constant voltage above 6.0 volts** - this would indicate that the signal circuit is shorted to another voltage supply.
    4. **If the signal reading has a constant 5.0 volts** - this indicates an open further downstream in the circuitry. Most likely the temp sensor or the temp sensor ground circuit. **Continue to step 4.**
3. Disconnect the temp sensor and ECU harness connectors and check the temp sensor signal circuit for high resistance and short to ground. If the signal circuit checks good, check all connectors in the system for pushed out, spread, corroded or dirty terminals before condemning a ECU. If all of the connectors check good, replace the ECU in accordance with the service information.
4. To check the temp sensor, move the test lead over and back probe the temp sensor ground circuit at the temp sensor harness connector.

TYPICAL CIRCUIT LOW DIAGNOSTICS:

1. To quickly eliminate the temp sensor as a possible cause with an **active** circuit low fault, disconnect the temp sensor harness connector while monitoring for the circuit high fault to become active on the scan

tool.

    1. If the circuit high fault becomes active when the sensor is disconnected, the temp sensor is most likely faulty.
    2. If the circuit high fault does not become active, **continue to step 2.**
2. Disconnect the ECU harness connector to isolate the circuit. Check the temp signal circuit for continuity to both chassis ground and the sensor ground circuit.
    1. If there is continuity to either, repair the signal circuit for a short to ground or the sensor ground circuit.
    2. If the signal circuit is not shorted, replace the ECU in accordance with the service information.

TYPICAL CIRCUIT HIGH DIAGNOSTICS:

1. Disconnect the temp sensor harness connector and measure the temp sensor signal circuit voltage with the ignition on. The signal circuit voltage should be between 4.9 and 5.6 volts.
    1. If battery voltage is present, repair the sensor signal circuit for a short to another voltage supply circuit.
    2. If the voltage is correct, **continue to step 2.** .
2. With an active fault, monitor the scan tool and connect a jumper across the terminals with the ignition on. Typically, the temp sensor signal voltage should change to 0 volts on the scan tool with the jumper in place. If the voltage data read is not available, check for the circuit low fault to set with the jumper in place. If either result occurs, the temp sensor is faulty.
    1. If either result occurs, the temp sensor is faulty.
    2. If the voltage does not change to 0 volts or the circuit low fault is not present with the jumper in place, **continue to step 3.** .
3. Check the resistance of the temp sensor signal circuit and temp sensor ground circuit. Typically the circuit resistance should be less than 5.0 Ohms.
    1. If there is an open or high resistance in either circuit, repair the circuit.
    2. If the temp sensor signal and ground circuits test good, and the voltage is still reading high or only the circuit high fault is present, use the wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning ECU. If no issues are found, replace the ECU in accordance with the service information.

TYPICAL PERFORMANCE/RATIONALITY DIAGNOSTICS:

NOTE: **Temp sensor performance faults typically set due to resistance in one of the circuits or a sensor that is stuck or drifted out of range. The (special tool #2064100080, Kit, Electrical Test Lead) can be used with the scan tool to test the wiring and controller.**

1. Disconnect the temp sensor harness connector and connect the Electrical Test Kit leads to the temp sensor harness connector.
2. Move the switch on the tool to open. The signal should read 5.0 volts and a circuit high DTC should be active or pending on the scan tool.
3. Next flip the switch to the closed position. The signal should read 0 volts and a circuit low fault should be active or pending on the scan tool. If the scan tool reads as described in steps 2 and 3, it would indicate the wiring and ECU are good and the sensor is likely faulty. If there is voltage present between 0 and 5.0 volts with the test tool in the closed position it would indicate there is likely resistance in one of the circuits. **Continue to step a.**
    1. To determine which circuit has resistance, remove the test lead connected to the temp sensor ground circuit and connect it to a good chassis ground.
        - If the signal changes to 0 volts it would indicate the temp sensor ground has resistance. **Continue to step b.**

- If there is still voltage present it would indicate the temp sensor signal has resistance. **Continue to step b.**

2. Confirm the suspect circuit issue by isolating the suspect circuit and measuring the resistance of the circuit between the sensor and ECU harness connectors. If no resistance is measured, carefully check all connectors in the path of the circuit for spread or dirty/corroded terminals. If the circuits check good (no resistance), verify whether the issue is with the temp sensor or ECU. **Continue to step 4 or 5.**

4. **If a temp table is available** , the sensor and ECU can be verified in one of the following ways.
   1. Move the switch to adjust and connect an Ohmmeter to the test leads and dial the tool to a resistance value in the table. Connect both leads to the temp sensor harness connector with the ignition on and monitor the data in the scan tool for the proper reading. Use the tool to vary the resistance while monitoring the temp sensor signal temperature/voltage on the scan tool. If the reading matches the table, the temp sensor is likely faulty.
   2. If the temp sensor actual temperature can be acquired or reasonably estimated, measure the resistance across the terminals of the temp sensor and compare to the value in the table. If the resistance of the sensor is not in range of the table, the temp sensor is likely faulty.
5. **If a temp table is not available** for the sensor being tested, connect the Electrical Test Kit leads to the harness connector and flip the switch to adjust. With the ignition on, monitor the scan tool data and slowly adjust the resistance in the circuit. The temperature/voltage value should change with the resistance change. If the value changes as the resistance is varied it would indicate that the temp sensor is likely faulty.

VERIFYING AN ECU FAILURE: An ECU that is faulty and not able to properly read the signal can usually be determined when opening and shorting the circuits and monitoring the signal voltage and fault codes. If the expected voltage reads or DTCs do not occur when opening and jumping the connector, and the circuits are not shorted or open, it would indicate a faulty ECU. Before condemning and ECU, **always** carefully check all connectors in the path of the circuit for water intrusion, spread, pushed out, burnt or corroded terminals.

P00FD-00-BATTERY B STATE OF CHARGE PERFORMANCE

For a complete STARTING SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

NOTE: **The terminology of the relays in this procedure can be confusing. To add clarity the Power Control Relay is the relay that makes and breaks the connection between the two Batteries. The PCR Control Relay is in the PDC and is controlled by the Powertrain Control Module (PCM) using a Low Side Driver (LSD). The relay can be removable or a Printed Circuit Board (PCB) relay depending on vehicle configuration. The PCR Control Relay provides the power supply to operate the Power Control Relay.**

The Engine Stop/Start (ESS) system uses a **Power Control Relay (PCR)** and two Batteries to eliminate the voltage drop in the system voltage during an Auto-start event. This allows the consumer electronics and vehicle modules subsystems to continue to function in a normal manner. The Power Control Relay is connected in-line between the Main (Cranking) Battery and the Auxiliary (Vehicle) Battery. The Power Control Relay is normally closed when de-energized, connecting the two Batteries. When the Power Control Relay is energized, the relay opens and breaks the connection between the Batteries.

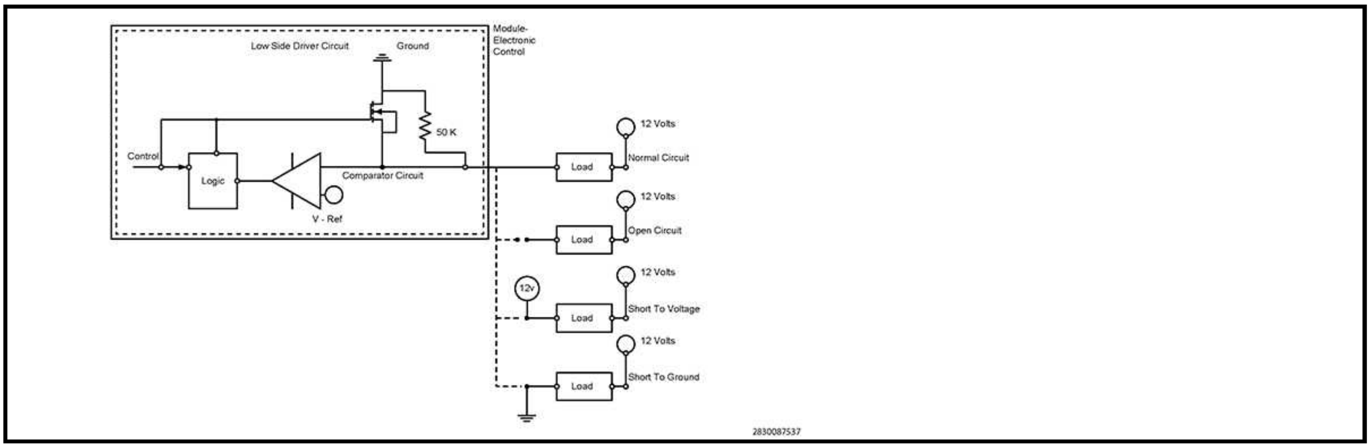
The engine starting and charging systems are connected directly to the Main Battery. When the Power Control Relay is closed (de-energized), the Auxiliary Battery is charged from the Main Battery. Therefore, if the Power Control Relay is stuck on (open), the Auxiliary Battery will not charge.

When ESS is active, and an **Auto-start crank event is initiated** , the **Power Control Relay** is temporarily energized when 12.0 volts is supplied from the output of the **PCR Control Relay in the PDC** . When the Power Control Relay is energized it breaks the connection and allows the Batteries to work independently. When this occurs, the Main Battery is used to crank and start the engine. The Auxiliary Battery, which is now solely connected to the PDC and is not affected by cranking, can maintain full Battery voltage to the rest of the vehicle modules and subsystems.

Typical Low Side Driver Operation and Fault Detection: This type of driver circuit is generally used for relay control, solenoid control or a similar type of driver device. The PCM provides a ground to operate the device when switched on. The ground could be constant or Pulse Width Modulated (PWM). The PCM also provides fault detection for the device, wiring and internal driver. Fault detection can be done by monitoring voltage on the circuit, current draw, or a combination of both. For diagnostic purposes the PCM uses an internal pull down diagnostic resistor connected in series and a voltage reference (V-Ref) comparator for fault detection:

- **Circuit Open and Circuit Low Detection:** The PCM monitors for an **open circuit** and **short to ground** when the driver is switched off. When switched off, the available voltage passes through the device and the **internal pull down resistor** connected in series. The voltage at the **comparator circuit** should be close to Battery voltage since the majority of the voltage drop occurs through the diagnostic resistor. If the available voltage is less than the V-Ref, a fault is set. In this scenario the V-Ref would be slightly below Battery voltage. **An alternative method of fault detection for an open or short to ground** that is used is to monitor current draw when the internal driver is switched on. If the module does not detect any current draw it determines that the component or circuitry is open. Excessive current draw detected would indicate a short to ground.
- **Circuit High Detection:** The PCM monitors for a **short to voltage** when the driver is switched on. When the driver is switched on providing a path to ground through the transistor, the available voltage should be pulled low, near zero volts since the **comparator circuit** is monitoring the ground side of the device. If the voltage is greater than V-Ref, a fault is detected. In this scenario V-Ref would be slightly above zero volts.

NOTE: **A load that has a resistance that is below manufacturer specification, or a second load device shorted to the low side driver circuit can cause excessive current draw on the internal driver. The driver will be switched off to protect against overheating and damaging the driver. In this instance the Circuit High fault may be detected because the available voltage on the comparator circuit is above V-Ref.**



DIAGNOSTIC OVERVIEW - STOP/START SYSTEM AND AUXILIARY BATTERY STATE OF CHARGE (SOC)

PCM DIAGNOSTICS: It is important for the Power Control Relay to operate properly to allow the Auxiliary Battery to charge correctly with the engine running and be disconnected during an Engine Stop/Start (ESS) Auto-start event. The PCM runs continuous diagnostics to determine if the Power Control Relay is stuck in the On (open) or Off (closed) positions.

DIAGNOSTIC OVERVIEW OF SYSTEM:

- **Ignition Crank Sense Diagnostic:** The PCM monitors the Ignition Crank Sense circuit voltage when engine cranking is commanded. The Ignition Crank Sense circuit is connected to the Starter Solenoid Feed circuit inside the PDC. When engine cranking is commanded the PCM expects to see battery voltage at the Ignition Crank Sense circuit. If no voltage is detected a fault is set.

- If the engine is able to crank when the feedback circuit performance fault is active it eliminates the battery supply, Starter Relays and Starter as possible causes for the fault setting. If the engine does not crank when the feedback circuit performance fault is active the Ignition Crank Sense circuit is not the possible cause.

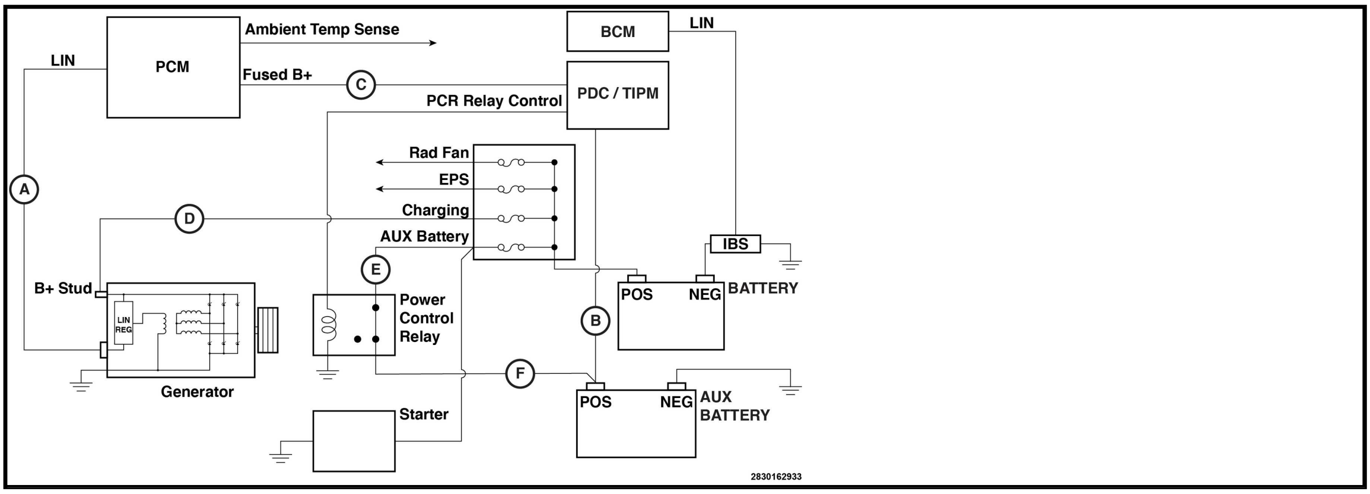
- **Stuck Starter Relay Diagnostic:** After the engine is initially started, the Powertrain Control Module (PCM) will command one of the Starter Relays closed and the other Starter Relay open and monitor the Ignition Crank Sense circuit for voltage. It will then open the closed relay and close the open relay and monitor the Ignition Crank Sense circuit for voltage. If there is voltage present on the feedback circuit during either of these tests, then the relay that was commanded off when voltage was detected is determined to be stuck closed and a performance fault is set against that relay.

POWER CONTROL RELAY DIAGNOSTIC: DISCLAIMER: The generic graphic below is used for reference to show how the components are configured in the system. It is not specific to any particular vehicle. Refer to the wiring and service information for the specific layout of the components for the vehicle that you are working on.

- **Diagnostic 1 - Auxiliary Battery Disconnected:** During an initial key start, the Power Control Relay is commanded on **(open)** and the Auxiliary Battery SOC is evaluated. If the Fused B+ voltage (C) to the Powertrain Control Module (PCM) is so low that the PCM experiences a reset during the initial key-on or engine crank event, the **PCM will set P00FD and ESS will be disabled.**

  NOTE: **This will cause a no crank condition. On the next key cycle the DTC will be active. The PCM will de-energize the Power Control Relay with an active DTC which will connect the Main Battery to the Auxiliary Battery, allowing the PCM to power up and allow engine cranking.**

- **Diagnostic 2 - Auxiliary Battery Depleted:** During an ESS Auto-start event, the Power Control Relay is temporarily commanded on (open) disconnecting the Main and Auxiliary Batteries from each other (E and F). This allows the Auxiliary Battery SOC to be separately monitored by the PCM. If the Auxiliary Battery voltage drops below a calibrated threshold (approximately 8.0 volts) during the ESS Auto-start event, the **PCM will set P00FD and ESS will be disabled.**
- **Diagnostic 3 - Auxiliary Battery is Depleting:** During the ESS Auto-start event, if the Auxiliary Battery voltage drops below a calibrated threshold the PCM will increment a counter by 1. ESS will be disabled for a short period to allow the Auxiliary Battery to charge before being re-enabled and tested again. If the voltage returns above a calibrated threshold on the next Auto-start event, the counter will decrement by 1. If the voltage is still below the calibrated threshold on the next Auto-start event, the counter will increment by 1 again. If the counter reaches 10 counts, the **PCM will set P00FD and ESS will be disabled.**
- **Diagnostic 4 - Power Control Relay Stuck Off:** During the ESS Auto-start event, if the PCM detects little or no difference (delta) between the Auxiliary Battery voltage and Main Battery voltage (C and IBS LIN feedback), the **PCM will set P2AF6 and ESS will be disabled.**
- **Diagnostic 5 - Auxiliary Battery Disconnected from Main Battery:** During normal engine operation, when the vehicle is not in an ESS Auto-start event, the Power Control Relay is commanded off (closed), connecting the Main and Auxiliary Batteries together (E and F) to allow the Auxiliary Battery to charge. If the difference (delta) between Auxiliary Battery voltage and Main Battery voltage (C and IBS LIN feedback) is more than a calibrated threshold, the **PCM will set P2AF5 and ESS will be disabled.**



SIMPLE DIAGNOSTIC STRATEGY:

- **The diagnostic for the P00FD fault** is basically designed to detect a discharging, discharged or disconnected Auxiliary Battery any time there is a disconnect between the two Batteries. It detects this if the Fused B+ voltage to the PCM drops low enough to cause a PCM reset when disconnected from the Main/Cranking Battery. This fault will detect a faulty Auxiliary Battery, or wiring issue between the Auxiliary Battery, PDC and Battery Supply circuit (B and C) and the PCM.
- **The P2AF5-Power Control Relay Stuck On description can be misleading.** Since the diagnostic is using a comparison of the voltage between the two Batteries as an indicator, it is more likely to have an issue in the wiring between either Battery and the Power Control Relay (E or F). The only way for the relay to be stuck on **(open)** would be if the internal contacts were physically stuck on, or the Fused B+ output from the PCR Control Relay were shorted to voltage. Both of these conditions are possible but not very likely. **A quick way to check for the Power Control Relay being stuck on (open)** would be to measure the voltage at each of the posts at the Power Control Relay with the engine running and the charging system active. If the Power Control Relay is stuck open the voltage on the Auxiliary Battery side will be lower than the voltage on the Main Battery side of the relay. If the voltage is the same on both sides, the relay is not open. If the voltage is equal to the charging system voltage at both terminals, the wiring issue is most likely on the Auxiliary Battery side of the relay. If the voltage is equal to the Auxiliary Battery voltage at both terminals, the wiring issue is most likely on the Main Battery side of the relay.
- **The P2AF6-Power Control Relay Stuck Off diagnostic** is checking for the disconnection between the Batteries to occur when the Power Control Relay is energized during an initial Auto-start event. **Anything that can cause the relay not to energize can set this fault,** including a wiring issue with either the Fused B+ output from the PCR Control Relay in the PDC or the Power Control Relay Ground circuit. These are the two circuits that control the Power Control Relay operation. They do not have separate control circuit faults associated with them. If there is an open or short in one of these circuits the stuck off rationality fault sets.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Ignition on.
- Power Control Relay (PCR) is commanded open.
- DTC P00FD is not already active.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Auxiliary Battery is disconnected at Key On before an Ignition Start event.
- The PCM detects that the Auxiliary Battery voltage is below 7.98 Volts when the PCR is commanded open.

- The PCM detects that the Auxiliary Battery voltage is below 10.30 Volts during an ESS Engine Start event.

DEFAULT ACTION

- This is a non-MIL DTC.
- Engine Start/Stop (ESS) events are disabled.

POSSIBLE CAUSES

Possible Causes
OPEN AUXILIARY BATTERY FUSE (150A) IN THE FUSE ARRAY
POOR CONNECTION AT THE PCR STUDS
POOR CONNECTION AT BATTERY POSITIVE OR NEGATIVE CABLE ENDS
HIGH RESISTANCE IN THE AUXILIARY BATTERY GROUND
HIGH RESISTANCE IN THE AUXILIARY BATTERY POSITIVE CABLE
PCR CONTROL RELAY OUTPUT CIRCUIT SHORTED TO VOLTAGE
PCR CONTROL RELAY (ON PCB INSIDE PDC) IS STUCK ON
POWER CONTROL RELAY (PCR) STUCK ON (OPEN)
FAULTY AUXILIARY BATTERY
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding.

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
   1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

      Are there any applicable Service Bulletins or Flash updates?

      Yes

      - Perform the applicable repair.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 2
2. **CHECK FOR OTHER DTCS**
   1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
   2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.

      Are there any PCR Control Relay Control circuit or Charging System DTCs present?

      Yes

      - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

      No

      - Go To 3

3. **CHECK RELEVANT CONNECTIONS AND FUSES**
    1. Check the Auxiliary Battery Fuse (150A) in the Fuse Array for an open condition.
    2. Check that the connections at both Main and Auxiliary Batteries are clean and tight.
    3. Check that the connections at the PCR studs are clean and tight.

    Were any issues found with the fuses or connections?

    Yes

    - Make the necessary repairs.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 4
4. **CHECK THE BATTERY STATE OF CHARGE FOR BOTH MAIN AND AUXILIARY BATTERIES**
    1. Disconnect the Negative Cable from the both Batteries.
    2. Use the (special tool #GR8-1220KIT-CHRY, AGM Battery Tester/Charger Station)or equivalent to load test both Batteries.

    Did both Batteries pass the load test?

    Yes

    - Go To 5

    No

    - Recharge or replace the Battery that failed and retest.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
5. **CHECK THE POWER CONTROL RELAY FOR PROPER OPERATION**
    1. Turn the ignition off.
    2. Reconnect both Battery Negative Cables.
    3. Remove the C2 and C3 terminals from the Power Control Relay.

    NOTE: **These circuits are still connected to Battery voltage. Be careful to insulate and/or isolate the cable so that it cannot make contact with any engine ground.**

    4. Measure the voltage at both the C2 and C3 harness terminals.

    Is the voltage at or near battery voltage at both C2 and C3 terminals?

    Yes

    - Go To 6

    No

    - Repair the circuit for an open or high resistance. Be certain to verify that any applicable fuses and connections are in good condition.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE POWER CONTROL RELAY FOR PROPER RESISTANCE**
    1. Check the PCR relay output side for continuity by measuring the resistance between the studs for C2 and C3.

       Is the resistance below 3.0 ohms?

       Yes

       - A poor connection may have been the cause of the DTC. Reconnect all terminals, verifying that all connections are clean and tight.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 7
7. **CHECK THE PCR CONTROL CIRCUIT FOR VOLTAGE**

   NOTE: **The PCR should only be energized when commanded by the PCM during Auto Start events.**

    1. Remove the C1 harness connector from the PCR.
    2. Turn the ignition on.
    3. Measure the PCR Control Relay Output at the C1 harness connector.

       Is voltage present?

       Yes

       - Check the PCR Control Relay Output for a short to voltage and repair as necessary. If no short to voltage is found, replace the PDC in accordance with Service Information.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 8
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
8. **REPLACE THE POWER CONTROL RELAY AND RETEST FOR DTCS**
    1. Turn the ignition off.
    2. Replace the PCR in accordance with the Service Information.
    3. Connect all disconnected harness connectors.
    4. Turn the ignition on.
    5. With the scan tool, erase all DTCs.
    6. Turn the ignition off for a minimum of 10.0 seconds.
    7. Turn the ignition on.
    8. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    9. With the scan tool, read DTCs.

       Did the DTC return?

       Yes

- Go To 9

No

- Replacing the faulty PCR repaired the fault.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0107-MANIFOLD ABSOLUTE PRESSURE SENSOR CIRCUIT LOW

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Manifold Absolute Pressure (MAP) Sensor is a transducer that varies resistance according to pressure changes in the Intake Manifold. The MAP Sensor signal provides the Powertrain Control Module (PCM) with an indication of the current air pressure within the Intake Manifold. The PCM uses this information to help calculate fuel delivery. The PCM supplies 5.0 volts to the MAP Sensor on a 5-Volt Reference circuit and provides a ground on a low reference circuit. The MAP Sensor provides a voltage signal to the PCM on a signal circuit relative to the pressure changes. The PCM receives the Barometric Pressure (BARO) Sensor reading from the MAP Sensor with the ignition on, before the engine is cranking or running.

NOTE: **Do not use shop air to clean out the MAP Sensor when diagnosing a MAP Sensor related fault as this will cause internal damage to the sensor.**

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the ignition on.
- Battery voltage greater than 10.4 volts.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Manifold Absolute Pressure (MAP) Sensor input voltage signal is below 0.10 - 0.15 volts for 0.08 seconds.

DEFAULT ACTION

- The MIL will illuminate.
- The ETC light will flash.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
5-VOLT SUPPLY CIRCUIT OPEN OR SHORTED
5-VOLT SUPPLY CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
MAP SENSOR PRESSURE SIGNAL CIRCUIT SHORTED TO GROUND
MAP SENSOR PRESSURE SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
MANIFOLD ABSOLUTE PRESSURE (MAP) SENSOR
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read and record DTCs in all Electronic Control Units (ECUs) on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.

4. Turn the ignition off for a minimum of 10.0 seconds.
5. Turn the ignition on.
6. Using the When Monitored Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **ISOLATE AND CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 3

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

3. **ISOLATE AND CHECK THE MAP SENSOR (K1) PRESSURE SIGNAL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as

a guide to follow the path of the circuit.

3. Connect the negative lead of the DVOM to a known good ground.
4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

No

- Go To 4

4. **ISOLATE AND CHECK THE MAP SENSOR (K1) PRESSURE SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

Is the resistance below 3.0 Ohms?

Yes

- Go To 6

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **ISOLATE AND CHECK THE MAP SENSOR (K1) PRESSURE SIGNAL CIRCUIT FOR A SHORT TO THE (K900) SENSOR GROUND CIRCUIT**
   1. The ignition must be off when checking for a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between the circuits being tested.**

   Is there continuity between the circuits?

   Yes

   - Repair the short between the circuits.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 6

6. **CONNECT A FUSED JUMPER BETWEEN THE MAP SENSOR (K1) PRESSURE SIGNAL CIRCUIT AND THE (F856) 5-VOLT SUPPLY CIRCUIT AT THE MAP SENSOR HARNESS CONNECTOR - VERIFY ABILITY OF THE PCM TO DETECT THE SENSOR SIGNAL CIRCUIT HIGH DTC**
   1. The Electronic Control Module (ECU) harness connectors must be connected to the ECU during this test step.
   2. Disconnect the sensor harness connector.
   3. With the ignition in the off position, connect a fused jumper between the sensor signal circuit and the 5-Volt Supply circuit at the sensor harness connector.
   4. Turn the ignition on.
   5. With the scan tool, read DTCs.

Does the scan tool display the SENSOR SIGNAL CIRCUIT HIGH DTC with the jumper in place?

Yes

- Replace the MAP Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 7

7. **CHECK RELATED HARNESS CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. With the scan tool, erase DTCs.
    9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    10. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0108-MANIFOLD ABSOLUTE PRESSURE SENSOR CIRCUIT HIGH

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Manifold Absolute Pressure (MAP) Sensor is a transducer that varies resistance according to pressure changes in the Intake Manifold. The MAP Sensor signal provides the Powertrain Control Module (PCM) with an indication of the current air pressure within the Intake Manifold. The PCM uses this information to help calculate fuel delivery. The PCM supplies 5.0 volts to the MAP Sensor on a 5-Volt Reference circuit and provides a ground on a low reference circuit. The MAP Sensor provides a voltage signal to the PCM on a signal circuit relative to the pressure changes. The PCM receives the Barometric Pressure (BARO) Sensor reading from the MAP Sensor with the ignition on, before the engine is cranking or running.

NOTE: **Do not use shop air to clean out the MAP Sensor when diagnosing a MAP Sensor related fault as this will cause internal damage to the sensor.**

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the ignition on
- Battery voltage greater than 10.4 volts

SET CONDITION

- The PCM detects that the MAP Sensor input voltage is above 4.91 volts for 0.08 seconds.

DEFAULT ACTION

- The MIL will illuminate.
- The ETC light will flash.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
MAP SENSOR PRESSURE SIGNAL CIRCUIT SHORTED TO VOLTAGE
MAP SENSOR PRESSURE SIGNAL CIRCUIT SHORTED TO THE 5-VOLT SUPPLY CIRCUIT
MAP SENSOR PRESSURE SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
MANIFOLD ABSOLUTE PRESSURE (MAP) SENSOR
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to **PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .**

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

NOTE:	**The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

    Is the voltage above 5.2 volts?

    Yes

    - Go To 4

    No

    - Go To 5
4. **ISOLATE AND CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors

connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.

3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 11

5. **CHECK THE MAP SENSOR (K1) PRESSURE SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
   1. Measure the voltage on the (K1) MAP Signal circuit at the MAP Sensor harness connector.

   Is the voltage above 5.2 volts?

   Yes

   - Go To 6

   No

   - Go To 7

6. **ISOLATE AND CHECK THE MAP SENSOR (K1) PRESSURE SIGNAL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
   4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

NOTE: With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 11

7. **ISOLATE AND CHECK THE MAP SENSOR (K1) PRESSURE SIGNAL CIRCUIT FOR A SHORT TO THE (F856) 5-VOLT SUPPLY CIRCUIT**
   1. The ignition must be off when checking for a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: There should be no continuity between the circuits being tested.

Is there continuity between the circuits?

Yes

- Repair the short between the circuits.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 8

8. **ISOLATE AND CHECK THE MAP SENSOR (K1) PRESSURE SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.

5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 9

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

9. **ISOLATE AND CHECK THE (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 10

   No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CONNECT A FUSED JUMPER BETWEEN THE (K900) SENSOR GROUND CIRCUIT AND THE MAP SENSOR (K1) PRESSURE SIGNAL CIRCUIT AT THE MAP SENSOR HARNESS CONNECTOR - VERIFY ABILITY OF THE PCM TO DETECT THE SENSOR SIGNAL CIRCUIT LOW DTC**
    1. The Electronic Control Module (ECU) harness connectors must be connected to the ECU during this test step.
    2. Disconnect the sensor harness connector.
    3. With the ignition in the off position, connect a fused jumper between the sensor signal circuit and the 5-Volt Supply circuit at the sensor harness connector.
    4. Turn the ignition on.
    5. With the scan tool, read DTCs.

    Does the scan tool display the SENSOR SIGNAL CIRCUIT LOW DTC with the jumper in place?

    Yes

    - Replace the faulty sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 11
11. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.

8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
    - Test complete.

P0111-INTAKE AIR TEMPERATURE SENSOR 1 PERFORMANCE

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Intake Air Temperature (IAT) Sensor rationality diagnostic looks at the outputs of three temperature sensors and compares them under cold start conditions. Following a start to run delay time the outputs of the Ambient Air Temperature (AAT) Sensor, Engine Coolant Temperature (ECT) Sensor, and Intake Air Temperature (IAT) Sensors will be compared. If the ECT and AAT Sensors agree and the IAT Sensor does not agree, the IAT Sensor is declared as irrational. If declared irrational a second comparison will be done after a short drive cycle.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- After an engine off time of greater than 480 minutes.
- At ignition on the:
  - Ambient temperature reading is greater than -64B°C (-83.2B°F).
  - Engine coolant temperature reading is greater than -64B°C (-83.2B°F).
  - Intake air temperature reading is greater than -64B°C (-83.2B°F).
- After the engine is started and the vehicle is driven above 48.3 kph (30 mph) for 30 seconds a determination is made.

SET CONDITION

- The PCM compares the Ambient Air Temperature (AAT), Engine Coolant Temperature (ECT), and Intake Air Temperature (IAT) Sensor values. If one of the sensor values is not within 15B°C (27B°F) of the other temperature sensors for two consecutive trips, a DTC will set.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
HIGH RESISTANCE IN THE IAT SENSOR TEMP SIGNAL CIRCUIT
HIGH RESISTANCE IN THE SENSOR GROUND CIRCUIT
INTAKE AIR TEMPERATURE (IAT) SENSOR
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
    1. Turn the ignition off.
    2. Allow the vehicle to sit with the ignition off in an environment where the temperature is consistent and above -64B°C (83.2B°F) until the engine coolant temperature is equal to, or close to the environmental ambient temperature.
    3. Turn the ignition on.
    4. With a scan tool, compare the AAT, ECT, and IAT Sensor values.

    Is the Intake Air Temperature Sensor value within 15B°C (27B°F) of the other two sensor values?

    Yes

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

    No

    - Go To 2
2. **ISOLATE AND CHECK THE IAT SENSOR (K21) TEMP SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

    Is the resistance below 3.0 Ohms?

Yes

- Go To 3

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

3. **ISOLATE AND CHECK THE (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

Is the resistance below 3.0 Ohms?

Yes

- Go To 4

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE ABILITY OF THE PCM TO READ THE INTAKE AIR TEMPERATURE SENSOR SIGNAL**
    1. Connect the PCM C2 harness connector.
    2. Turn the ignition on.
    3. With the scan tool, read DTCs.

NOTE: **The P0113-INTAKE AIR TEMPERATURE SENSOR CIRCUIT HIGH DTC should display as active or pending with the Intake Air Temperature harness connector disconnected.**

4. Turn the ignition off.

5. Connect a jumper between the (K21) IAT Signal circuit and the (K900) Sensor Ground circuit at the Intake Air Temperature Sensor harness connector.
6. Turn the ignition on.
7. With the scan tool, read DTCs.

NOTE: **The P0112-INTAKE AIR TEMPERATURE SENSOR CIRCUIT LOW DTC should display as active or pending with the jumper in place.**

Do the DTCs display as described above?

Yes

- Replace the Intake Air Temperature Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.
   6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   9. With the scan tool, erase DTCs.
   10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
   11. With the scan tool, read DTCs.

   Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0112-INTAKE AIR TEMPERATURE SENSOR 1 CIRCUIT LOW

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Intake Air Temperature (IAT) Sensor is a variable resistor that functions as a normal two wire, 5-Volt sensor. The Powertrain Control Module (PCM) supplies the IAT Sensor with a 5-Volt signal and a filtered ground (return) circuit. For the IAT Sensor diagnostic, the PCM internally monitors the voltage on the signal circuit, which is converted into a temperature reading. If the voltage reads above the high calibrated threshold, or below the low calibrated threshold, a circuit high or low fault is set.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the ignition on.
- Battery voltage greater than 10.4 volts.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Intake Air Temperature (IAT) Sensor input voltage is below 0.43 volt for 2.24 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
IAT SENSOR TEMP CIRCUIT SHORTED TO GROUND
IAT SENSOR TEMP CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
INTAKE AIR TEMPERATURE (IAT) SENSOR
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

Are there any applicable Service Bulletins or Flash updates?

Yes

- Perform the applicable repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read and record DTCs in all Electronic Control Units (ECUs) on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **DISCONNECT THE IAT SENSOR HARNESS CONNECTOR AND VERIFY THE ABILITY OF THE PCM TO READ THE SENSOR SIGNAL HIGH DTC**
    1. The Electronic Control Unit (ECU) harness connectors must be connected to the ECU during this test step.
    2. With the ignition in the off position, disconnect the sensor harness connector.
    3. Turn the ignition on.
    4. With the scan tool, read DTCs.

    Does the scan tool display the SENSOR SIGNAL CIRCUIT HIGH DTC with the connector disconnected?

    Yes

    - Replace the faulty sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 4

4. **ISOLATE AND CHECK THE IAT SENSOR (K21) TEMP SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

        NOTE: **There should be no continuity between ground and the circuit being tested.**

        Is there continuity between ground and the circuit being tested?

        Yes

        - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Go To 5
5. **ISOLATE AND CHECK THE IAT SENSOR (K21) TEMP SIGNAL CIRCUIT FOR A SHORT TO THE (K900) SENSOR GROUND CIRCUIT**
    1. The ignition must be off when checking for a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

        NOTE: **There should be no continuity between the circuits being tested.**

        Is there continuity between the circuits?

        Yes

- Repair the short between the circuits.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.
   6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   9. With the scan tool, erase DTCs.
   10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
   11. With the scan tool, read DTCs.

   Did the DTC return?

   Yes

   - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - The wiring or poor connection problem has been repaired.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

DIAGNOSIS AND TESTING

P0113-INTAKE AIR TEMPERATURE SENSOR 1 CIRCUIT HIGH

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Intake Air Temperature (IAT) Sensor is a variable resistor that functions as a normal two wire, 5-Volt sensor. The Powertrain Control Module (PCM) supplies the IAT Sensor with a 5-Volt signal and a filtered ground (return) circuit. For the IAT Sensor diagnostic, the PCM internally monitors the voltage on the signal circuit, which is converted into a temperature reading. If the voltage reads above the high calibrated threshold, or below the low calibrated threshold, a circuit high or low fault is set.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- With the ignition on.
- battery voltage greater than 10.4 volts.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Intake Air Temperature (IAT) Sensor input voltage is above 4.9 - 4.95 volts depending on calibration for 2.24 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

POSSIBLE CAUSES
IAT SENSOR TEMP SIGNAL CIRCUIT SHORTED TO VOLTAGE
IAT SENSOR TEMP SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
INTAKE AIR TEMPERATURE (IAT) SENSOR
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

  - Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
   1. With the scan tool, read and record DTCs in all Electronic Control Units (ECUs) on the repair order.
   2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
   3. With the scan tool, erase all DTCs.
   4. Turn the ignition off for a minimum of 10.0 seconds.
   5. Turn the ignition on.
   6. Using the When Monitored Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
   7. With the scan tool, read DTCs.

   Did the DTC return?

   Yes

   - Go To 3

   No

   - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **CHECK THE IAT SENSOR (K21) TEMP SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
   1. Turn the ignition off.
   2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Turn the ignition on.
   4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

   NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

   Is the voltage above 5.2 volts?

   Yes

   - Go To 4

   No

   - Go To 5

4. **ISOLATE AND CHECK THE IAT SENSOR (K21) TEMP SIGNAL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Units (ECUs) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
   4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 8

5. **ISOLATE AND CHECK THE IAT SENSOR (K21) TEMP SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Units (ECUs) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

Is the resistance below 3.0 Ohms?

Yes

- Go To 6

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **ISOLATE AND CHECK THE (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**

1. The ignition must be off when checking the continuity of a circuit.
2. Isolate the circuit by disconnecting the Electronic Control Units (ECUs) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 7

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **CONNECT A FUSED JUMPER BETWEEN THE IAT SENSOR (K21) TEMP SIGNAL CIRCUIT AND THE (K900) SENSOR GROUND CIRCUIT AT THE IAT SENSOR HARNESS CONNECTOR - VERIFY ABILITY OF THE PCM TO DETECT THE SENSOR SIGNAL CIRCUIT LOW DTC**
   1. The Powertrain Control Module (PCM) harness connectors must be connected to the ECU during this test step.
   2. Disconnect the sensor harness connector.
   3. With the ignition in the off position, connect a fused jumper between the sensor signal circuit and the sensor ground circuit at the sensor harness connector.
   4. Turn the ignition on.
   5. With the scan tool, read DTCs.

   Does the scan tool display the SENSOR SIGNAL CIRCUIT LOW DTC with the jumper in place?

   Yes

   - Replace the faulty sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

- Go To 8

8. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0116-ENGINE COOLANT TEMPERATURE SENSOR PERFORMANCE

For a complete COOLING SYSTEM wiring diagram, **refer to the appropriate wiring information** .

DESCRIPTION AND OPERATION - ENGINE COOLANT TEMPERATURE (ECT) SENSOR

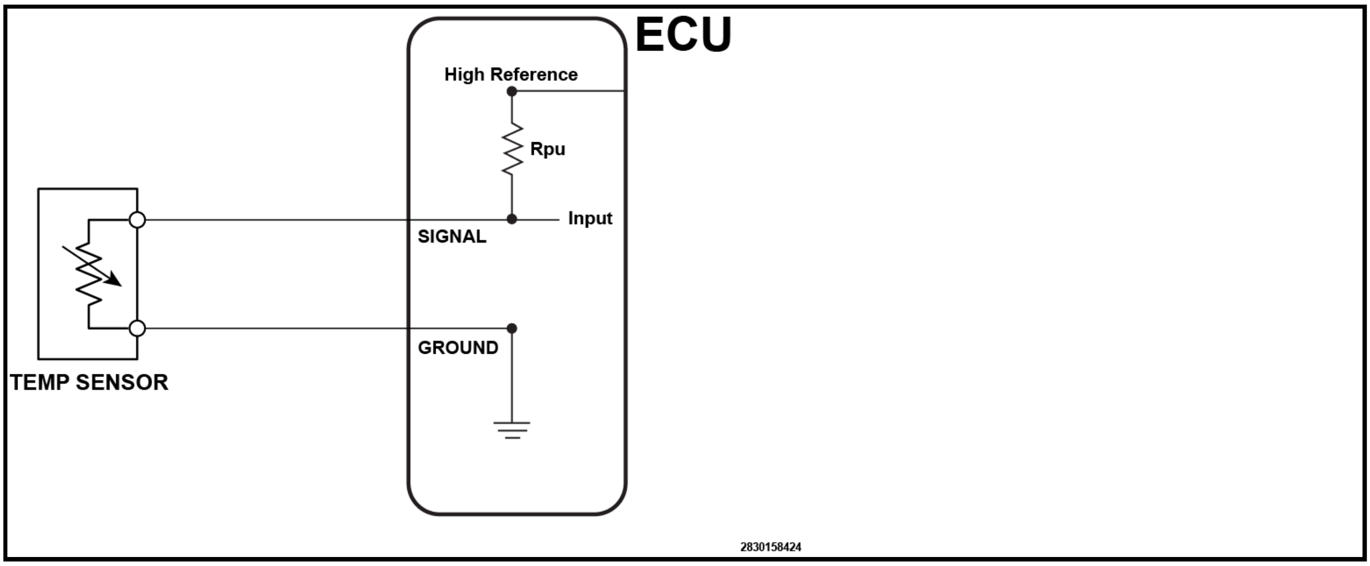
The Powertrain Control Module (PCM) monitors the ECT Sensor analog signal voltage. The ECT Sensor input signal is used with other sensor inputs in calculating fuel delivery and engine timing. The PCM also uses the ECT Sensor input for determining when to enable several OBD diagnostics. Each of these will impact emissions, which is why the ECT Sensor signal must be rationalized by the PCM.

The ECT Sensor rationality diagnostic looks at the outputs of three temperature sensors and compares them under cold start conditions. Following a start to run delay time the outputs of the Ambient Air Temperature (AAT) Sensor, Engine Coolant Temperature (ECT) Sensor, and Intake Air Temperature (IAT) Sensor will be compared. If the IAT and AAT Sensors agree and the coolant temperature does not agree, the ECT Sensor is declared as irrational. If declared irrational a second comparison will be done after a short drive cycle.

COMPONENT FUNCTIONAL DESCRIPTION - TWO WIRE TEMP SENSOR

GENERAL OPERATION: Temperature sensors are typically a variable resistor that functions as a normal two wire, 5.0 volt sensor. An Electronic Control Unit (ECU) supplies the Temp Sensor with a 5.0 volt reference signal and a filtered ground (return) circuit. The pull up resistor (Rpu) inside the ECU is a fixed resistance. The resistance in the sensor will change in relation to temperature. The resistors are configured in a simple series circuit with the ECU internally monitoring the voltage on the signal circuit, which is converted into a digital temperature reading. As the resistance of the component increases, the voltage on the signal circuit will also increase. The increased voltage on the signal circuit can be interpreted by the ECU as the temperature increasing or decreasing depending on the temp sensor and ECU software design.

- **Circuit Fault Diagnostics:** On a normally functioning sensor with no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts would set a circuit high/open fault. A voltage below approximately 0.10 volts will set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.
- **Performance Fault Diagnostics:** Since added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault, the module will check the signal for a plausible reading in some cases. This can be done using different methods. One common way is by comparing the sensor reading to other temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (I.E. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.



ANALOG TO DIGITAL SIGNAL DESCRIPTION

Electronic Control Modules read analog signal voltages and convert them to digital counts. Each count is an equal percentage of the voltage. This can be seen when viewing the voltages of some sensors or switches on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts on most sensors to a battery voltage reference on switches.

- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals have a high resolution (Ex. a sensor signal may be divided into 4096 counts, or 5.0 volts divided by 4096). This allows the module to read small changes over a wide range in a variable resistance sensor signal used for a temperature, pressure, or position sensors.
- Switches will typically have a low resolution since they are usually only reporting a few switch states (Ex. a switch may typically be divided into only 15-20 counts, or Battery voltage divided by 15). The highest and lowest one or two counts will be used for detecting opens or shorts if the switch signal is being rationalized. The remaining counts are divided up between the states being detected.

ENABLING CONDITIONS AND POSSIBLE CAUSES - ENGINE COOLANT TEMP SENSOR

MONITORING CONDITIONS
Circuit Low/High Faults - With the ignition on, battery voltage above a calibrated threshold. **Performance Fault** - With the ignition on after an eight hour cold soak on the previous engine off cycle. Ambient Air, Intake Air, Engine Oil and Engine Coolant Temperature values are above -64B°C (-83B°F).

FAULT SETTING CRITERIA
Circuit Low Fault - The sensor signal voltage is below a calibrated threshold. The threshold is typically in the 0.1 volt range. **Circuit High Fault** - The sensor signal voltage is above a calibrated threshold. The threshold is typically in the 4.9 volt range. **Performance Fault** - The sensor signal voltage is irrational - typically not within 10B°C - 15B°C (18B°F - 27B°F) of the other engine temp sensors. **NOTE:** **The fail values will increase if a block heater is detected.**

POSSIBLE CAUSES
TEMP SENSOR HARNESS CONNECTOR DAMAGED OR NOT CONNECTED COMPLETELY (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH FAULT)
TEMP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR RETURN CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
FAULTY TEMP SENSOR (OPEN, SHORTED OR DRIFTED OUT OF RANGE)
FAULTY POWERTRAIN CONTROL MODULE (PCM)

DIAGNOSTIC OVERVIEW

TEMP SENSOR ECU DIAGNOSTICS:

- **Circuit Fault Diagnostics:** With a normally functioning sensor that has no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts will typically set a circuit high/open fault. A voltage below approximately 0.10 volts will typically set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.

- **Performance Fault Diagnostics:** Added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault. The module will check the signal for a plausible reading in most cases. This can be done using different methods. One common way is by comparing the sensor reading to other temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (Ex. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.

PRELIMINARY DIAGNOSTIC CHECKS

1. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the ECU. Low Battery voltage can cause a DTC.
3. Circuit faults should typically be diagnosed before rationality/performance faults.
4. Check the component harness connector(s) for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the component harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.
2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connections issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the appropriate wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

Intermittent testing for a circuit low/high fault with the Mopar Scope:

1. Back probe and connect the scope lead to the temp sensor signal circuit.
2. Monitor the circuit voltage while wiggle testing the wiring harness.
3. If you are not able to monitor the scope signal voltage during wiggle testing, set up a trigger to catch an intermittent condition. Set the trigger for voltage above 4.9 volts for an intermittent circuit high fault or below 0.1 volts for a circuit low fault.

DIAGNOSTIC TEST - TWO WIRE TEMP SENSOR

NOTE: **If a repair is performed to the AAT Sensor wiring, the sensor is replaced, or the BCM connector is disconnected during testing to correct an active DTC, the vehicle must be driven for a minimum of 5 minutes above 15 mph to update the AAT temp signal before the DTC will go stored and can be erased.**

NOTE: **The AAT Sensor is an individually serviceable component. If the measured resistance from the AAT Sensor does not meet the values from the Technical Data information, then only the sensor should be replaced and not the entire mirror assembly.**

NOTE: **There are multiple test methods listed below. The first two tests are a complete system diagnostic of the wiring and sensor. The remaining tests are broken up by the failure modes. There can be advantages to using each method. All of the methods do not need to be performed. Pick the best test method based on accessibility, ease of testing, availability of test equipment. It is a good practice to perform a complete check of the wiring in case of calibration issues. Failure to perform a complete check of the wiring may lead to unnecessary replacement of the component or ECU. In some cases it may be beneficial to use parts of each method to test for different failure modes.**

COMPLETE CIRCUIT DIAGNOSTICS USING THE ELECTRICAL TEST LEAD KIT:

1. Check the ECU, signal and sensor ground circuits together to determine if the temp sensor is faulty. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the temp signal and sensor ground circuits at the temp sensor harness connector. Move the switch on the Electrical Test Lead Kit between the open and closed positions while monitoring the scan tool. If monitoring for faults, the circuit high fault should set when switched to the open position and the circuit low fault should set when switched to the closed position. If the sensor voltage is available on the scan tool, monitor the voltage readings. The voltage should be 5.0 volts when switched to the open position and 0.0 volts when switched to the closed position. Move the switch to adjust and use the tool to vary the resistance while monitoring the ECU signal voltage on the scan tool. **Pick the result from a, b, or c below that best matches the results.**

1. **If the faults set as described and the signal voltage is 5.0 volts and 0.0 volts** - the ECU and temp sensor circuits are testing good. The temp sensor is most likely faulty or has a poor connection at the harness connector. Check the temp sensor harness connector for pushed out, spread, corroded or dirty terminals before condemning the sensor. The internal resistance of the sensor can be measured and compared to the table (if available) to verify a faulty sensor.
2. **If the signal voltage is stuck low or only the circuit low fault sets** - the most likely cause is the temp sensor signal circuit shorted to chassis ground or the temp sensor ground circuit. Check the temp sensor signal circuit for a short to ground, or to the temp sensor ground circuit. If the signal circuit is not shorted, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals before condemning an ECU. If no issues are found, the ECU is most likely faulty.
3. **If the signal voltage is stuck high or only the circuit high fault sets** - the most likely cause is an open or very high resistance in the temp sensor signal or temp sensor ground circuit. **Continue to step d.**
4. **If the signal reading on the scan tool shows voltage present when switched to closed** - remove the test lead from the sensor ground circuit and connect it to a good chassis ground while observing the voltage on the scan tool. If the voltage drops to 0.0 volts the resistance is in the temp sensor ground circuit. If the voltage is still present the resistance is in the temp sensor signal circuit. Check the appropriate circuit for high resistance. Typically, it should be less than 3.0 Ohms. If the circuits check good, **continue to step e.**
5. **If the circuits are checked and do not have excessive resistance** - Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the ECU. If no issues are found, replace the ECU in accordance with the service information.

COMPLETE CIRCUIT DIAGNOSTICS USING CONVENTIONAL VOLTAGE TESTING WITH A DVOM:

1. Verify the temp sensor and ECU harness connectors are connected and locked properly.
2. Turn the ignition on. Back probe and measure the voltage on the temp sensor signal circuit at the Fuel Pump harness connector. Pick the result below that best matches the voltage reading.
    1. **If the signal voltage is reading between 0.1 and 4.9 volts** - the temp sensor signal is most likely giving a legitimate reading. If the circuit fault is active and the voltage reading on the scan tool does not match the DVOM voltage reading, the ECU is likely faulty.
    2. **If the signal measures a constant 0.0 volts** - this indicates that the temp sensor signal circuit is shorted to ground or has an open between the ECU and temp sensor. If the circuit high fault is set, the most likely failure is an open in the temp sensor signal circuit. If the circuit low fault is set, the

most likely failure is a short to ground in the temp sensor signal circuit or possibly a faulty sensor (disconnecting the temp sensor harness connector and checking for the circuit high fault to become active would indicate that the temp sensor is most likely faulty). **Continue to step 3.**

  3. **If the signal reading has a constant voltage above 6.0 volts** - this would indicate that the signal circuit is shorted to another voltage supply.
  4. **If the signal reading has a constant 5.0 volts** - this indicates an open further downstream in the circuitry. Most likely the temp sensor or the temp sensor ground circuit. **Continue to step 4.**

3. Disconnect the temp sensor and ECU harness connectors and check the temp sensor signal circuit for high resistance and short to ground. If the signal circuit checks good, check all connectors in the system for pushed out, spread, corroded or dirty terminals before condemning a ECU. If all of the connectors check good, replace the ECU in accordance with the service information.
4. To check the temp sensor, move the test lead over and back probe the temp sensor ground circuit at the temp sensor harness connector.

TYPICAL CIRCUIT LOW DIAGNOSTICS:

1. To quickly eliminate the temp sensor as a possible cause with an **active** circuit low fault, disconnect the temp sensor harness connector while monitoring for the circuit high fault to become active on the scan tool.
   1. If the circuit high fault becomes active when the sensor is disconnected, the temp sensor is most likely faulty.
   2. If the circuit high fault does not become active, **continue to step 2.**
2. Disconnect the ECU harness connector to isolate the circuit. Check the temp signal circuit for continuity to both chassis ground and the sensor ground circuit.
   1. If there is continuity to either, repair the signal circuit for a short to ground or the sensor ground circuit.
   2. If the signal circuit is not shorted, replace the ECU in accordance with the service information.

TYPICAL CIRCUIT HIGH DIAGNOSTICS:

1. Disconnect the temp sensor harness connector and measure the temp sensor signal circuit voltage with the ignition on. The signal circuit voltage should be between 4.9 and 5.6 volts.
   1. If battery voltage is present, repair the sensor signal circuit for a short to another voltage supply circuit.
   2. If the voltage is correct, **continue to step 2.** .
2. With an active fault, monitor the scan tool and connect a jumper across the terminals with the ignition on. Typically, the temp sensor signal voltage should change to 0 volts on the scan tool with the jumper in place. If the voltage data read is not available, check for the circuit low fault to set with the jumper in place. If either result occurs, the temp sensor is faulty.
   1. If either result occurs, the temp sensor is faulty.
   2. If the voltage does not change to 0 volts or the circuit low fault is not present with the jumper in place, **continue to step 3.** .
3. Check the resistance of the temp sensor signal circuit and temp sensor ground circuit. Typically the circuit resistance should be less than 5.0 Ohms.
   1. If there is an open or high resistance in either circuit, repair the circuit.
   2. If the temp sensor signal and ground circuits test good, and the voltage is still reading high or only the circuit high fault is present, Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning ECU. If no issues are found, replace the ECU in accordance with the service information.

TYPICAL PERFORMANCE/RATIONALITY DIAGNOSTICS:

NOTE: Temp sensor performance faults typically set due to resistance in one of the circuits or a sensor that is stuck or drifted out of range. The (special tool #2064100080, Kit, Electrical Test Lead) can be used with the scan tool to test the wiring and controller.

1. Disconnect the temp sensor harness connector and connect the Electrical Test Kit leads to the temp sensor harness connector.
2. Move the switch on the tool to open. The signal should read 5.0 volts and a circuit high DTC should be active or pending on the scan tool.
3. Next flip the switch to the closed position. The signal should read 0 volts and a circuit low fault should be active or pending on the scan tool. If the scan tool reads as described in steps 2 and 3, it would indicate the wiring and ECU are good and the sensor is likely faulty. If there is voltage present between 0 and 5.0 volts with the test tool in the closed position it would indicate there is likely resistance in one of the circuits. **Continue to step a.**
    1. To determine which circuit has resistance, remove the test lead connected to the temp sensor ground circuit and connect it to a good chassis ground.
        - If the signal changes to 0 volts it would indicate the temp sensor ground has resistance. **Continue to step b.**
        - If there is still voltage present it would indicate the temp sensor signal has resistance. **Continue to step b.**
    2. Confirm the suspect circuit issue by isolating the suspect circuit and measuring the resistance of the circuit between the sensor and ECU harness connectors. If no resistance is measured, carefully check all connectors in the path of the circuit for spread or dirty/corroded terminals. If the circuits check good (no resistance), verify whether the issue is with the temp sensor or ECU. **Continue to step 4 or 5.**
4. **If a temp table is available** , the sensor and ECU can be verified in one of the following ways.
    1. Move the switch to adjust and connect an Ohmmeter to the test leads and dial the tool to a resistance value in the table. Connect both leads to the temp sensor harness connector with the ignition on and monitor the data in the scan tool for the proper reading. Use the tool to vary the resistance while monitoring the temp sensor signal temperature/voltage on the scan tool. If the reading matches the table, the temp sensor is likely faulty.
    2. If the temp sensor actual temperature can be acquired or reasonably estimated, measure the resistance across the terminals of the temp sensor and compare to the value in the table. If the resistance of the sensor is not in range of the table, the temp sensor is likely faulty.
5. **If a temp table is not available** for the sensor being tested, connect the Electrical Test Kit leads to the harness connector and flip the switch to adjust. With the ignition on, monitor the scan tool data and slowly adjust the resistance in the circuit. The temperature/voltage value should change with the resistance change. If the value changes as the resistance is varied it would indicate that the temp sensor is likely faulty.

VERIFYING AN ECU FAILURE: An ECU that is faulty and not able to properly read the signal can usually be determined when opening and shorting the circuits and monitoring the signal voltage and fault codes. If the expected voltage reads or DTCs do not occur when opening and jumping the connector, and the circuits are not shorted or open, it would indicate a faulty ECU. Before condemning and ECU, **always** carefully check all connectors in the path of the circuit for water intrusion, spread, pushed out, burnt or corroded terminals.

P0117-ENGINE COOLANT TEMPERATURE SENSOR CIRCUIT LOW

For a complete COOLING SYSTEM wiring diagram, **refer to the appropriate wiring information** .

DESCRIPTION AND OPERATION - ENGINE COOLANT TEMPERATURE (ECT) SENSOR

The Powertrain Control Module (PCM) monitors the ECT Sensor analog signal voltage. The ECT Sensor input signal is used with other sensor inputs in calculating fuel delivery and engine timing. The PCM also uses the

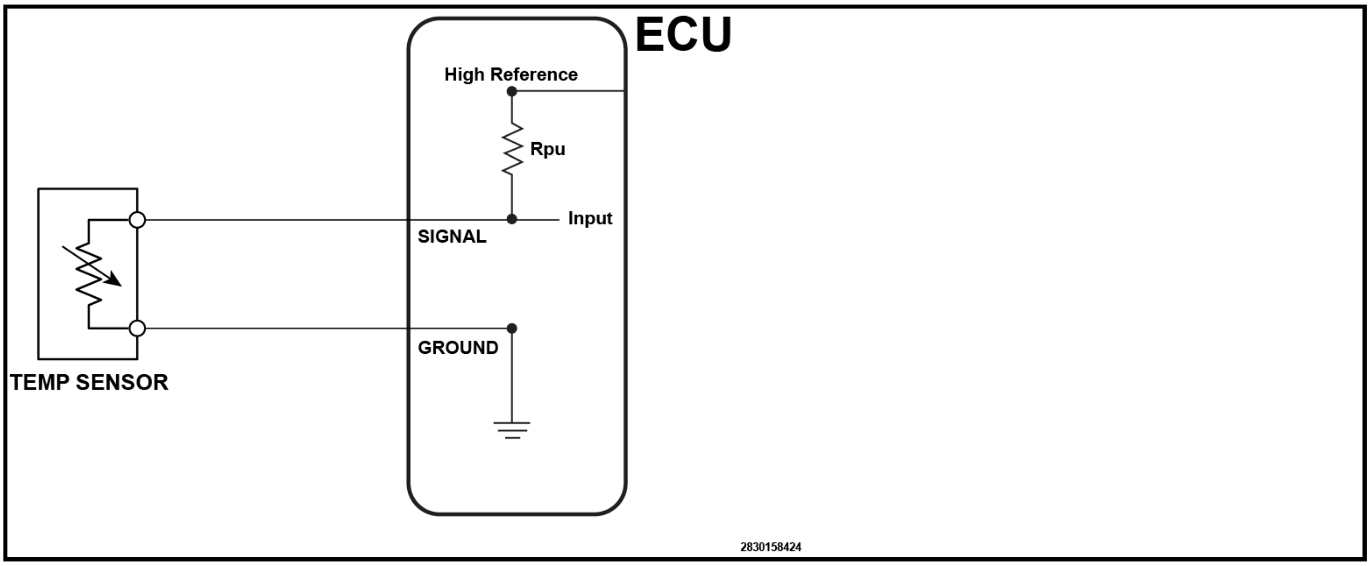
ECT Sensor input for determining when to enable several OBD diagnostics. Each of these will impact emissions, which is why the ECT Sensor signal must be rationalized by the PCM.

The ECT Sensor rationality diagnostic looks at the outputs of three temperature sensors and compares them under cold start conditions. Following a start to run delay time the outputs of the Ambient Air Temperature (AAT) Sensor, Engine Coolant Temperature (ECT) Sensor, and Intake Air Temperature (IAT) Sensor will be compared. If the IAT and AAT Sensors agree and the coolant temperature does not agree, the ECT Sensor is declared as irrational. If declared irrational a second comparison will be done after a short drive cycle.

COMPONENT FUNCTIONAL DESCRIPTION - TWO WIRE TEMP SENSOR

GENERAL OPERATION: Temperature sensors are typically a variable resistor that functions as a normal two wire, 5.0 volt sensor. An Electronic Control Unit (ECU) supplies the Temp Sensor with a 5.0 volt reference signal and a filtered ground (return) circuit. The pull up resistor (Rpu) inside the ECU is a fixed resistance. The resistance in the sensor will change in relation to temperature. The resistors are configured in a simple series circuit with the ECU internally monitoring the voltage on the signal circuit, which is converted into a digital temperature reading. As the resistance of the component increases, the voltage on the signal circuit will also increase. The increased voltage on the signal circuit can be interpreted by the ECU as the temperature increasing or decreasing depending on the temp sensor and ECU software design.

- **Circuit Fault Diagnostics:** On a normally functioning sensor with no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts would set a circuit high/open fault. A voltage below approximately 0.10 volts will set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.
- **Performance Fault Diagnostics:** Since added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault, the module will check the signal for a plausible reading in some cases. This can be done using different methods. One common way is by comparing the sensor reading to other temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (I.E. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.



ANALOG TO DIGITAL SIGNAL DESCRIPTION

Electronic Control Modules read analog signal voltages and convert them to digital counts. Each count is an equal percentage of the voltage. This can be seen when viewing the voltages of some sensors or switches on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts on most sensors to a battery voltage reference on switches.

- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals have a high resolution (Ex. a sensor signal may be divided into 4096 counts, or 5.0 volts divided by 4096). This allows the module to read small changes over a wide range in a variable resistance sensor signal used for a temperature, pressure, or position sensors.

- Switches will typically have a low resolution since they are usually only reporting a few switch states (Ex. a switch may typically be divided into only 15-20 counts, or Battery voltage divided by 15). The highest and lowest one or two counts will be used for detecting opens or shorts if the switch signal is being rationalized. The remaining counts are divided up between the states being detected.

ENABLING CONDITIONS AND POSSIBLE CAUSES - ENGINE COOLANT TEMP SENSOR

MONITORING CONDITIONS
Circuit Low/High Faults - With the ignition on, battery voltage above a calibrated threshold. **Performance Fault** - With the ignition on after an eight hour cold soak on the previous engine off cycle. Ambient Air, Intake Air, Engine Oil and Engine Coolant Temperature values are above -64B°C (-83B°F).

FAULT SETTING CRITERIA
Circuit Low Fault - The sensor signal voltage is below a calibrated threshold. The threshold is typically in the 0.1 volt range. **Circuit High Fault** - The sensor signal voltage is above a calibrated threshold. The threshold is typically in the 4.9 volt range. **Performance Fault** - The sensor signal voltage is irrational - typically not within 10B°C - 15B°C (18B°F - 27B°F) of the other engine temp sensors. **NOTE:** **The fail values will increase if a block heater is detected.**

POSSIBLE CAUSES
TEMP SENSOR HARNESS CONNECTOR DAMAGED OR NOT CONNECTED COMPLETELY (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH FAULT)
TEMP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR RETURN CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
FAULTY TEMP SENSOR (OPEN, SHORTED OR DRIFTED OUT OF RANGE)
FAULTY POWERTRAIN CONTROL MODULE (PCM)

DIAGNOSTIC OVERVIEW

TEMP SENSOR ECU DIAGNOSTICS:

- **Circuit Fault Diagnostics:** With a normally functioning sensor that has no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts will typically set a circuit high/open fault. A voltage below approximately 0.10 volts will typically set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.
- **Performance Fault Diagnostics:** Added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault. The module will check the signal for a plausible reading in most cases. This can be done using different methods. One common way is by comparing the sensor reading to other

temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (Ex. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.

PRELIMINARY DIAGNOSTIC CHECKS

1. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the ECU. Low Battery voltage can cause a DTC.
3. Circuit faults should typically be diagnosed before rationality/performance faults.
4. Check the component harness connector(s) for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the component harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.
2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connections issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the appropriate wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

Intermittent testing for a circuit low/high fault with the Mopar Scope:

1. Back probe and connect the scope lead to the temp sensor signal circuit.
2. Monitor the circuit voltage while wiggle testing the wiring harness.

3. If you are not able to monitor the scope signal voltage during wiggle testing, set up a trigger to catch an intermittent condition. Set the trigger for voltage above 4.9 volts for an intermittent circuit high fault or below 0.1 volts for a circuit low fault.

DIAGNOSTIC TEST - TWO WIRE TEMP SENSOR

NOTE: **If a repair is performed to the AAT Sensor wiring, the sensor is replaced, or the BCM connector is disconnected during testing to correct an active DTC, the vehicle must be driven for a minimum of 5 minutes above 15 mph to update the AAT temp signal before the DTC will go stored and can be erased.**

NOTE: **The AAT Sensor is an individually serviceable component. If the measured resistance from the AAT Sensor does not meet the values from the Technical Data information, then only the sensor should be replaced and not the entire mirror assembly.**

NOTE: **There are multiple test methods listed below. The first two tests are a complete system diagnostic of the wiring and sensor. The remaining tests are broken up by the failure modes. There can be advantages to using each method. All of the methods do not need to be performed. Pick the best test method based on accessibility, ease of testing, availability of test equipment. It is a good practice to perform a complete check of the wiring in case of calibration issues. Failure to perform a complete check of the wiring may lead to unnecessary replacement of the component or ECU. In some cases it may be beneficial to use parts of each method to test for different failure modes.**

COMPLETE CIRCUIT DIAGNOSTICS USING THE ELECTRICAL TEST LEAD KIT:

1. Check the ECU, signal and sensor ground circuits together to determine if the temp sensor is faulty. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the temp signal and sensor ground circuits at the temp sensor harness connector. Move the switch on the Electrical Test Lead Kit between the open and closed positions while monitoring the scan tool. If monitoring for faults, the circuit high fault should set when switched to the open position and the circuit low fault should set when switched to the closed position. If the sensor voltage is available on the scan tool, monitor the voltage readings. The voltage should be 5.0 volts when switched to the open position and 0.0 volts when switched to the closed position. Move the switch to adjust and use the tool to vary the resistance while monitoring the ECU signal voltage on the scan tool. **Pick the result from a, b, or c below that best matches the results.**

1. **If the faults set as described and the signal voltage is 5.0 volts and 0.0 volts** - the ECU and temp sensor circuits are testing good. The temp sensor is most likely faulty or has a poor connection at the harness connector. Check the temp sensor harness connector for pushed out, spread, corroded or dirty terminals before condemning the sensor. The internal resistance of the sensor can be measured and compared to the table (if available) to verify a faulty sensor.
2. **If the signal voltage is stuck low or only the circuit low fault sets** - the most likely cause is the temp sensor signal circuit shorted to chassis ground or the temp sensor ground circuit. Check the temp sensor signal circuit for a short to ground, or to the temp sensor ground circuit. If the signal circuit is not shorted, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals before condemning an ECU. If no issues are found, the ECU is most likely faulty.
3. **If the signal voltage is stuck high or only the circuit high fault sets** - the most likely cause is an open or very high resistance in the temp sensor signal or temp sensor ground circuit. **Continue to step d.**
4. **If the signal reading on the scan tool shows voltage present when switched to closed** - remove the test lead from the sensor ground circuit and connect it to a good chassis ground while observing the voltage on the scan tool. If the voltage drops to 0.0 volts the resistance is in the temp sensor ground circuit. If the voltage is still present the resistance is in the temp sensor signal circuit. Check the appropriate circuit for high resistance. Typically, it should be less than 3.0 Ohms. If the circuits check good, **continue to step e.**
5. **If the circuits are checked and do not have excessive resistance** - Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the ECU. If no issues are found, replace the ECU in accordance with the service information.

COMPLETE CIRCUIT DIAGNOSTICS USING CONVENTIONAL VOLTAGE TESTING WITH A DVOM:

1. Verify the temp sensor and ECU harness connectors are connected and locked properly.
2. Turn the ignition on. Back probe and measure the voltage on the temp sensor signal circuit at the Fuel Pump harness connector. Pick the result below that best matches the voltage reading.
    1. **If the signal voltage is reading between 0.1 and 4.9 volts** - the temp sensor signal is most likely giving a legitimate reading. If the circuit fault is active and the voltage reading on the scan tool does not match the DVOM voltage reading, the ECU is likely faulty.
    2. **If the signal measures a constant 0.0 volts** - this indicates that the temp sensor signal circuit is shorted to ground or has an open between the ECU and temp sensor. If the circuit high fault is set, the most likely failure is an open in the temp sensor signal circuit. If the circuit low fault is set, the most likely failure is a short to ground in the temp sensor signal circuit or possibly a faulty sensor (disconnecting the temp sensor harness connector and checking for the circuit high fault to become active would indicate that the temp sensor is most likely faulty). **Continue to step 3.**
    3. **If the signal reading has a constant voltage above 6.0 volts** - this would indicate that the signal circuit is shorted to another voltage supply.
    4. **If the signal reading has a constant 5.0 volts** - this indicates an open further downstream in the circuitry. Most likely the temp sensor or the temp sensor ground circuit. **Continue to step 4.**
3. Disconnect the temp sensor and ECU harness connectors and check the temp sensor signal circuit for high resistance and short to ground. If the signal circuit checks good, check all connectors in the system for pushed out, spread, corroded or dirty terminals before condemning a ECU. If all of the connectors check good, replace the ECU in accordance with the service information.
4. To check the temp sensor, move the test lead over and back probe the temp sensor ground circuit at the temp sensor harness connector.

TYPICAL CIRCUIT LOW DIAGNOSTICS:

1. To quickly eliminate the temp sensor as a possible cause with an **active** circuit low fault, disconnect the temp sensor harness connector while monitoring for the circuit high fault to become active on the scan

tool.

    1. If the circuit high fault becomes active when the sensor is disconnected, the temp sensor is most likely faulty.
    2. If the circuit high fault does not become active, **continue to step 2.**
2. Disconnect the ECU harness connector to isolate the circuit. Check the temp signal circuit for continuity to both chassis ground and the sensor ground circuit.
    1. If there is continuity to either, repair the signal circuit for a short to ground or the sensor ground circuit.
    2. If the signal circuit is not shorted, replace the ECU in accordance with the service information.

TYPICAL CIRCUIT HIGH DIAGNOSTICS:

1. Disconnect the temp sensor harness connector and measure the temp sensor signal circuit voltage with the ignition on. The signal circuit voltage should be between 4.9 and 5.6 volts.
    1. If battery voltage is present, repair the sensor signal circuit for a short to another voltage supply circuit.
    2. If the voltage is correct, **continue to step 2.** .
2. With an active fault, monitor the scan tool and connect a jumper across the terminals with the ignition on. Typically, the temp sensor signal voltage should change to 0 volts on the scan tool with the jumper in place. If the voltage data read is not available, check for the circuit low fault to set with the jumper in place. If either result occurs, the temp sensor is faulty.
    1. If either result occurs, the temp sensor is faulty.
    2. If the voltage does not change to 0 volts or the circuit low fault is not present with the jumper in place, **continue to step 3.** .
3. Check the resistance of the temp sensor signal circuit and temp sensor ground circuit. Typically the circuit resistance should be less than 5.0 Ohms.
    1. If there is an open or high resistance in either circuit, repair the circuit.
    2. If the temp sensor signal and ground circuits test good, and the voltage is still reading high or only the circuit high fault is present, Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning ECU. If no issues are found, replace the ECU in accordance with the service information.

TYPICAL PERFORMANCE/RATIONALITY DIAGNOSTICS:

NOTE: **Temp sensor performance faults typically set due to resistance in one of the circuits or a sensor that is stuck or drifted out of range. The (special tool #2064100080, Kit, Electrical Test Lead) can be used with the scan tool to test the wiring and controller.**

1. Disconnect the temp sensor harness connector and connect the Electrical Test Kit leads to the temp sensor harness connector.
2. Move the switch on the tool to open. The signal should read 5.0 volts and a circuit high DTC should be active or pending on the scan tool.
3. Next flip the switch to the closed position. The signal should read 0 volts and a circuit low fault should be active or pending on the scan tool. If the scan tool reads as described in steps 2 and 3, it would indicate the wiring and ECU are good and the sensor is likely faulty. If there is voltage present between 0 and 5.0 volts with the test tool in the closed position it would indicate there is likely resistance in one of the circuits. **Continue to step a.**
    1. To determine which circuit has resistance, remove the test lead connected to the temp sensor ground circuit and connect it to a good chassis ground.
        - If the signal changes to 0 volts it would indicate the temp sensor ground has resistance. **Continue to step b.**

- If there is still voltage present it would indicate the temp sensor signal has resistance. **Continue to step b.**

2. Confirm the suspect circuit issue by isolating the suspect circuit and measuring the resistance of the circuit between the sensor and ECU harness connectors. If no resistance is measured, carefully check all connectors in the path of the circuit for spread or dirty/corroded terminals. If the circuits check good (no resistance), verify whether the issue is with the temp sensor or ECU. **Continue to step 4 or 5.**

4. **If a temp table is available** , the sensor and ECU can be verified in one of the following ways.
   1. Move the switch to adjust and connect an Ohmmeter to the test leads and dial the tool to a resistance value in the table. Connect both leads to the temp sensor harness connector with the ignition on and monitor the data in the scan tool for the proper reading. Use the tool to vary the resistance while monitoring the temp sensor signal temperature/voltage on the scan tool. If the reading matches the table, the temp sensor is likely faulty.
   2. If the temp sensor actual temperature can be acquired or reasonably estimated, measure the resistance across the terminals of the temp sensor and compare to the value in the table. If the resistance of the sensor is not in range of the table, the temp sensor is likely faulty.
5. **If a temp table is not available** for the sensor being tested, connect the Electrical Test Kit leads to the harness connector and flip the switch to adjust. With the ignition on, monitor the scan tool data and slowly adjust the resistance in the circuit. The temperature/voltage value should change with the resistance change. If the value changes as the resistance is varied it would indicate that the temp sensor is likely faulty.

VERIFYING AN ECU FAILURE: An ECU that is faulty and not able to properly read the signal can usually be determined when opening and shorting the circuits and monitoring the signal voltage and fault codes. If the expected voltage reads or DTCs do not occur when opening and jumping the connector, and the circuits are not shorted or open, it would indicate a faulty ECU. Before condemning and ECU, **always** carefully check all connectors in the path of the circuit for water intrusion, spread, pushed out, burnt or corroded terminals.

P0118-ENGINE COOLANT TEMPERATURE SENSOR CIRCUIT HIGH

For a complete COOLING SYSTEM wiring diagram, **refer to the appropriate wiring information** .

DESCRIPTION AND OPERATION - ENGINE COOLANT TEMPERATURE (ECT) SENSOR

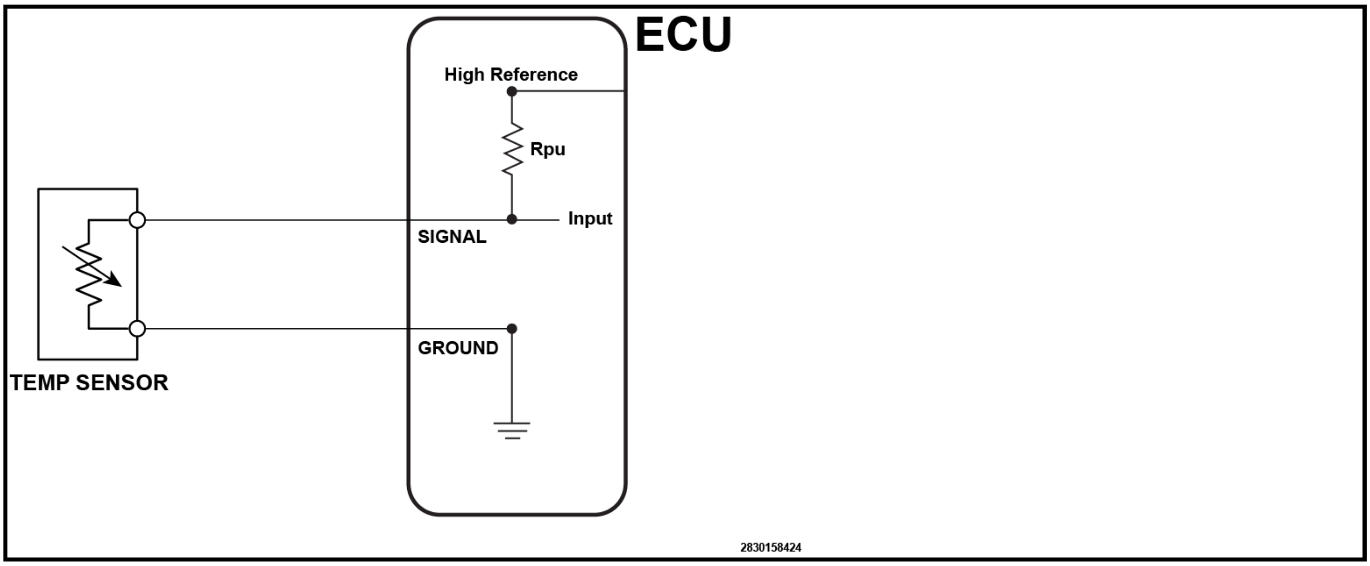
The Powertrain Control Module (PCM) monitors the ECT Sensor analog signal voltage. The ECT Sensor input signal is used with other sensor inputs in calculating fuel delivery and engine timing. The PCM also uses the ECT Sensor input for determining when to enable several OBD diagnostics. Each of these will impact emissions, which is why the ECT Sensor signal must be rationalized by the PCM.

The ECT Sensor rationality diagnostic looks at the outputs of three temperature sensors and compares them under cold start conditions. Following a start to run delay time the outputs of the Ambient Air Temperature (AAT) Sensor, Engine Coolant Temperature (ECT) Sensor, and Intake Air Temperature (IAT) Sensor will be compared. If the IAT and AAT Sensors agree and the coolant temperature does not agree, the ECT Sensor is declared as irrational. If declared irrational a second comparison will be done after a short drive cycle.

COMPONENT FUNCTIONAL DESCRIPTION - TWO WIRE TEMP SENSOR

GENERAL OPERATION: Temperature sensors are typically a variable resistor that functions as a normal two wire, 5.0 volt sensor. An Electronic Control Unit (ECU) supplies the Temp Sensor with a 5.0 volt reference signal and a filtered ground (return) circuit. The pull up resistor (Rpu) inside the ECU is a fixed resistance. The resistance in the sensor will change in relation to temperature. The resistors are configured in a simple series circuit with the ECU internally monitoring the voltage on the signal circuit, which is converted into a digital temperature reading. As the resistance of the component increases, the voltage on the signal circuit will also increase. The increased voltage on the signal circuit can be interpreted by the ECU as the temperature increasing or decreasing depending on the temp sensor and ECU software design.

- **Circuit Fault Diagnostics:** On a normally functioning sensor with no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts would set a circuit high/open fault. A voltage below approximately 0.10 volts will set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.
- **Performance Fault Diagnostics:** Since added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault, the module will check the signal for a plausible reading in some cases. This can be done using different methods. One common way is by comparing the sensor reading to other temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (I.E. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.



ANALOG TO DIGITAL SIGNAL DESCRIPTION

Electronic Control Modules read analog signal voltages and convert them to digital counts. Each count is an equal percentage of the voltage. This can be seen when viewing the voltages of some sensors or switches on the scan tool. The values will change in blocks (Ex. 0.08v, 0.12v, 0.16v or 8 Pa, 16 Pa, 24 Pa etc.). The signal voltage could be anywhere from 5.0 volts on most sensors to a battery voltage reference on switches.

- The resolution of the signal is determined by the required precision of the input by the ECU. Typically, sensor signals have a high resolution (Ex. a sensor signal may be divided into 4096 counts, or 5.0 volts divided by 4096). This allows the module to read small changes over a wide range in a variable resistance sensor signal used for a temperature, pressure, or position sensors.
- Switches will typically have a low resolution since they are usually only reporting a few switch states (Ex. a switch may typically be divided into only 15-20 counts, or Battery voltage divided by 15). The highest and lowest one or two counts will be used for detecting opens or shorts if the switch signal is being rationalized. The remaining counts are divided up between the states being detected.

ENABLING CONDITIONS AND POSSIBLE CAUSES - ENGINE COOLANT TEMP SENSOR

MONITORING CONDITIONS
Circuit Low/High Faults - With the ignition on, battery voltage above a calibrated threshold. **Performance Fault** - With the ignition on after an eight hour cold soak on the previous engine off cycle. Ambient Air, Intake Air, Engine Oil and Engine Coolant Temperature values are above -64B°C (-83B°F).

FAULT SETTING CRITERIA
Circuit Low Fault - The sensor signal voltage is below a calibrated threshold. The threshold is typically in the 0.1 volt range.

FAULT SETTING CRITERIA
Circuit High Fault - The sensor signal voltage is above a calibrated threshold. The threshold is typically in the 4.9 volt range. **Performance Fault** - The sensor signal voltage is irrational - typically not within 10B°C - 15B°C (18B°F - 27B°F) of the other engine temp sensors. **NOTE:** **The fail values will increase if a block heater is detected.**

POSSIBLE CAUSES
TEMP SENSOR HARNESS CONNECTOR DAMAGED OR NOT CONNECTED COMPLETELY (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO GROUND (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT (CIRCUIT LOW FAULT)
TEMP SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE (CIRCUIT HIGH FAULT)
TEMP SENSOR SIGNAL CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
TEMP SENSOR RETURN CIRCUIT OPEN/HIGH RESISTANCE (CIRCUIT HIGH/PERFORMANCE FAULT)
FAULTY TEMP SENSOR (OPEN, SHORTED OR DRIFTED OUT OF RANGE)
FAULTY POWERTRAIN CONTROL MODULE (PCM)

DIAGNOSTIC OVERVIEW

TEMP SENSOR ECU DIAGNOSTICS:

- **Circuit Fault Diagnostics:** With a normally functioning sensor that has no circuit issues, the signal voltage should never read 5.0 volts or 0.0 volts. This allows the module the capability of diagnosing an open or short in the sensor or wiring. As a general rule, a voltage reading above approximately 4.9 volts will typically set a circuit high/open fault. A voltage below approximately 0.10 volts will typically set a circuit Low fault. Calibrated thresholds can vary slightly from module to module and vehicle to vehicle.
- **Performance Fault Diagnostics:** Added resistance in the sensor or circuitry can cause an irrational reading and no circuit fault. The module will check the signal for a plausible reading in most cases. This can be done using different methods. One common way is by comparing the sensor reading to other temperature sensors. With this method the module will compare the sensors at a time when the readings should be within a calibrated threshold of each other (Ex. Ignition on after a cold soak). Another method could be to monitor for the temperature to increase or decrease when turning on or off a device that is being controlled by the ECU. In either case, an irrational reading can set a sensor performance fault.

PRELIMINARY DIAGNOSTIC CHECKS

1. Check for any Service Bulletins, Star On-line Cases or ECU flash updates that apply for the DTC or symptom.
2. Check for any Battery voltage DTCs in the ECU. Low Battery voltage can cause a DTC.
3. Circuit faults should typically be diagnosed before rationality/performance faults.
4. Check the component harness connector(s) for proper connection at the component. Verify that the connector is completely plugged in and properly locked prior to disconnecting for testing. Disconnect the component harness connector and check for water intrusion and any pushed out, damaged, corroded, burnt, or spread terminals.

CHECK FOR AN ACTIVE OR INTERMITTENT CONDITION

Checking for an active DTC or condition: Read and record all DTCs and Freeze Frame Data. Run and save a vehicle scan report for alter use if needed. Review the Freeze Frame data, When Monitored and Set Conditions. Erase all DTCS and operate the vehicle or system in accordance with the these conditions attempting to duplicate the DTC or condition. If a DTC returns or the condition is present continue with the diagnostic procedure. If the DTC or condition is not present, review the Intermittent Condition Testing information.

Intermittent Condition Testing: A DTC can be stored for any number of reasons. If a DTC is not active review and check the following items below;

1. The DTC may be stored because the diagnostic has not run during the current ignition cycle. Review the scan tool Freeze Frame Data, along with the When Monitored and Set Conditions, and attempt to operate the vehicle or system in the similar conditions to allow the diagnostic to run. Some diagnostics may not be easily duplicate, such as some temperature sensor rationality diagnostics which require extended cold soaks. Other diagnostics may require several environmental conditions or extensive enable conditions difficult to duplicate. For these cases it may be best to simply check for proper operation of the components or systems to verify if failure mode is present before attempting to diagnose the system.
2. Electronic Control Modules can be affected by temperature or software issues. Always check for any flash updates that may be related to the DTC or failure mode before continuing to diagnose an intermittent condition.
3. Poor wiring harness connections are a big contributor to intermittent electrical connections. Always check for any Service Bulletins that may apply to the DTC or failure mode before continuing to diagnose an intermittent condition. If no bulletins apply check for connections issues by wiggle testing any wiring harness the circuitry passes through. A good practice is too watch for a DTC to become active or scan tool data to change. An even better method is to attach the Mopar Scope to the circuitry and wiggle test the wiring. Review the scope pattern looking for intermittent opens in the circuitry during the wiggle test. Poor Battery system voltage or poor ground connections can affect systems in different or odd ways. Check the Battery or Batteries for proper charge and operation along with proper connections. Use the appropriate wiring information to identify and check any chassis ground connections related to the systems or components being diagnosed. Verify that connectors are locked in properly at the components, modules and any in-line connectors in the system. Look for pushed out, corroded, spread, burnt, or broken terminals at each connector.
4. Mechanical and electrical components can fail intermittently due to temperature changes or vibration during driving.

Intermittent testing for a circuit low/high fault with the Mopar Scope:

1. Back probe and connect the scope lead to the temp sensor signal circuit.
2. Monitor the circuit voltage while wiggle testing the wiring harness.
3. If you are not able to monitor the scope signal voltage during wiggle testing, set up a trigger to catch an intermittent condition. Set the trigger for voltage above 4.9 volts for an intermittent circuit high fault or below 0.1 volts for a circuit low fault.

DIAGNOSTIC TEST - TWO WIRE TEMP SENSOR

NOTE: **If a repair is performed to the AAT Sensor wiring, the sensor is replaced, or the BCM connector is disconnected during testing to correct an active DTC, the vehicle must be driven for a minimum of 5 minutes above 15 mph to update the AAT temp signal before the DTC will go stored and can be erased.**

NOTE: **The AAT Sensor is an individually serviceable component. If the measured resistance from the AAT Sensor does not meet the values from the Technical Data information, then only the sensor should be replaced and not the entire mirror assembly.**

NOTE: **There are multiple test methods listed below. The first two tests are a complete system diagnostic of the wiring and sensor. The remaining tests are broken up by the failure modes. There can be advantages to using each method. All of the methods do not need to be performed. Pick the best test method based on accessibility, ease of testing, availability of test equipment. It is a good practice to perform a complete check of the wiring in case of calibration issues. Failure to perform a complete check of the wiring may lead to unnecessary replacement of the component or ECU. In some cases it may be beneficial to use parts of each method to test for different failure modes.**

COMPLETE CIRCUIT DIAGNOSTICS USING THE ELECTRICAL TEST LEAD KIT:

1. Check the ECU, signal and sensor ground circuits together to determine if the temp sensor is faulty. Connect the (special tool #2064100080, Kit, Electrical Test Lead) to the temp signal and sensor ground circuits at the temp sensor harness connector. Move the switch on the Electrical Test Lead Kit between the open and closed positions while monitoring the scan tool. If monitoring for faults, the circuit high fault should set when switched to the open position and the circuit low fault should set when switched to the closed position. If the sensor voltage is available on the scan tool, monitor the voltage readings. The voltage should be 5.0 volts when switched to the open position and 0.0 volts when switched to the closed position. Move the switch to adjust and use the tool to vary the resistance while monitoring the ECU signal voltage on the scan tool. **Pick the result from a, b, or c below that best matches the results.**

    1. **If the faults set as described and the signal voltage is 5.0 volts and 0.0 volts** - the ECU and temp sensor circuits are testing good. The temp sensor is most likely faulty or has a poor connection at the harness connector. Check the temp sensor harness connector for pushed out, spread, corroded or dirty terminals before condemning the sensor. The internal resistance of the sensor can be measured and compared to the table (if available) to verify a faulty sensor.
    2. **If the signal voltage is stuck low or only the circuit low fault sets** - the most likely cause is the temp sensor signal circuit shorted to chassis ground or the temp sensor ground circuit. Check the temp sensor signal circuit for a short to ground, or to the temp sensor ground circuit. If the signal circuit is not shorted, Use the appropriate wiring information to check all related harness connectors in the system for pushed out, spread, corroded or dirty terminals before condemning an ECU. If no issues are found, the ECU is most likely faulty.
    3. **If the signal voltage is stuck high or only the circuit high fault sets** - the most likely cause is an open or very high resistance in the temp sensor signal or temp sensor ground circuit. **Continue to step d.**
    4. **If the signal reading on the scan tool shows voltage present when switched to closed** - remove the test lead from the sensor ground circuit and connect it to a good chassis ground while observing

the voltage on the scan tool. If the voltage drops to 0.0 volts the resistance is in the temp sensor ground circuit. If the voltage is still present the resistance is in the temp sensor signal circuit. Check the appropriate circuit for high resistance. Typically, it should be less than 3.0 Ohms. If the circuits check good, **continue to step e.**

5. **If the circuits are checked and do not have excessive resistance** - Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning the ECU. If no issues are found, replace the ECU in accordance with the service information.

COMPLETE CIRCUIT DIAGNOSTICS USING CONVENTIONAL VOLTAGE TESTING WITH A DVOM:

1. Verify the temp sensor and ECU harness connectors are connected and locked properly.
2. Turn the ignition on. Back probe and measure the voltage on the temp sensor signal circuit at the Fuel Pump harness connector. Pick the result below that best matches the voltage reading.
    1. **If the signal voltage is reading between 0.1 and 4.9 volts** - the temp sensor signal is most likely giving a legitimate reading. If the circuit fault is active and the voltage reading on the scan tool does not match the DVOM voltage reading, the ECU is likely faulty.
    2. **If the signal measures a constant 0.0 volts** - this indicates that the temp sensor signal circuit is shorted to ground or has an open between the ECU and temp sensor. If the circuit high fault is set, the most likely failure is an open in the temp sensor signal circuit. If the circuit low fault is set, the most likely failure is a short to ground in the temp sensor signal circuit or possibly a faulty sensor (disconnecting the temp sensor harness connector and checking for the circuit high fault to become active would indicate that the temp sensor is most likely faulty). **Continue to step 3.**
    3. **If the signal reading has a constant voltage above 6.0 volts** - this would indicate that the signal circuit is shorted to another voltage supply.
    4. **If the signal reading has a constant 5.0 volts** - this indicates an open further downstream in the circuitry. Most likely the temp sensor or the temp sensor ground circuit. **Continue to step 4.**
3. Disconnect the temp sensor and ECU harness connectors and check the temp sensor signal circuit for high resistance and short to ground. If the signal circuit checks good, check all connectors in the system for pushed out, spread, corroded or dirty terminals before condemning a ECU. If all of the connectors check good, replace the ECU in accordance with the service information.
4. To check the temp sensor, move the test lead over and back probe the temp sensor ground circuit at the temp sensor harness connector.

TYPICAL CIRCUIT LOW DIAGNOSTICS:

1. To quickly eliminate the temp sensor as a possible cause with an **active** circuit low fault, disconnect the temp sensor harness connector while monitoring for the circuit high fault to become active on the scan tool.
    1. If the circuit high fault becomes active when the sensor is disconnected, the temp sensor is most likely faulty.
    2. If the circuit high fault does not become active, **continue to step 2.**
2. Disconnect the ECU harness connector to isolate the circuit. Check the temp signal circuit for continuity to both chassis ground and the sensor ground circuit.
    1. If there is continuity to either, repair the signal circuit for a short to ground or the sensor ground circuit.
    2. If the signal circuit is not shorted, replace the ECU in accordance with the service information.

TYPICAL CIRCUIT HIGH DIAGNOSTICS:

1. Disconnect the temp sensor harness connector and measure the temp sensor signal circuit voltage with the ignition on. The signal circuit voltage should be between 4.9 and 5.6 volts.

    1. If battery voltage is present, repair the sensor signal circuit for a short to another voltage supply circuit.
    2. If the voltage is correct, **continue to step 2.** .
2. With an active fault, monitor the scan tool and connect a jumper across the terminals with the ignition on. Typically, the temp sensor signal voltage should change to 0 volts on the scan tool with the jumper in place. If the voltage data read is not available, check for the circuit low fault to set with the jumper in place. If either result occurs, the temp sensor is faulty.
    1. If either result occurs, the temp sensor is faulty.
    2. If the voltage does not change to 0 volts or the circuit low fault is not present with the jumper in place, **continue to step 3.** .
3. Check the resistance of the temp sensor signal circuit and temp sensor ground circuit. Typically the circuit resistance should be less than 5.0 Ohms.
    1. If there is an open or high resistance in either circuit, repair the circuit.
    2. If the temp sensor signal and ground circuits test good, and the voltage is still reading high or only the circuit high fault is present, Use the appropriate wiring information to check all related harness connectors for pushed out, spread, corroded or dirty terminals before condemning ECU. If no issues are found, replace the ECU in accordance with the service information.

TYPICAL PERFORMANCE/RATIONALITY DIAGNOSTICS:

NOTE: **Temp sensor performance faults typically set due to resistance in one of the circuits or a sensor that is stuck or drifted out of range. The (special tool #2064100080, Kit, Electrical Test Lead) can be used with the scan tool to test the wiring and controller.**

1. Disconnect the temp sensor harness connector and connect the Electrical Test Kit leads to the temp sensor harness connector.
2. Move the switch on the tool to open. The signal should read 5.0 volts and a circuit high DTC should be active or pending on the scan tool.
3. Next flip the switch to the closed position. The signal should read 0 volts and a circuit low fault should be active or pending on the scan tool. If the scan tool reads as described in steps 2 and 3, it would indicate the wiring and ECU are good and the sensor is likely faulty. If there is voltage present between 0 and 5.0 volts with the test tool in the closed position it would indicate there is likely resistance in one of the circuits. **Continue to step a.**
    1. To determine which circuit has resistance, remove the test lead connected to the temp sensor ground circuit and connect it to a good chassis ground.
        - If the signal changes to 0 volts it would indicate the temp sensor ground has resistance. **Continue to step b.**
        - If there is still voltage present it would indicate the temp sensor signal has resistance. **Continue to step b.**
    2. Confirm the suspect circuit issue by isolating the suspect circuit and measuring the resistance of the circuit between the sensor and ECU harness connectors. If no resistance is measured, carefully check all connectors in the path of the circuit for spread or dirty/corroded terminals. If the circuits check good (no resistance), verify whether the issue is with the temp sensor or ECU. **Continue to step 4 or 5.**
4. **If a temp table is available** , the sensor and ECU can be verified in one of the following ways.
    1. Move the switch to adjust and connect an Ohmmeter to the test leads and dial the tool to a resistance value in the table. Connect both leads to the temp sensor harness connector with the ignition on and monitor the data in the scan tool for the proper reading. Use the tool to vary the resistance while monitoring the temp sensor signal temperature/voltage on the scan tool. If the reading matches the table, the temp sensor is likely faulty.
    2. If the temp sensor actual temperature can be acquired or reasonably estimated, measure the resistance across the terminals of the temp sensor and compare to the value in the table. If the

resistance of the sensor is not in range of the table, the temp sensor is likely faulty.

5. **If a temp table is not available** for the sensor being tested, connect the Electrical Test Kit leads to the harness connector and flip the switch to adjust. With the ignition on, monitor the scan tool data and slowly adjust the resistance in the circuit. The temperature/voltage value should change with the resistance change. If the value changes as the resistance is varied it would indicate that the temp sensor is likely faulty.

VERIFYING AN ECU FAILURE: An ECU that is faulty and not able to properly read the signal can usually be determined when opening and shorting the circuits and monitoring the signal voltage and fault codes. If the expected voltage reads or DTCs do not occur when opening and jumping the connector, and the circuits are not shorted or open, it would indicate a faulty ECU. Before condemning and ECU, **always** carefully check all connectors in the path of the circuit for water intrusion, spread, pushed out, burnt or corroded terminals.

P0121-THROTTLE POSITION SENSOR 1 PERFORMANCE

For a complete THROTTLE CONTROL SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Electronic Throttle Control (ETC) system uses two Throttle Position Sensors (TPS) to monitor the throttle blade position. TPS 1 and TPS 2 are located within the Throttle Body assembly. Each sensor has its own Signal circuit (TPS 1 or TPS 2). Both sensors share a common 5-Volt Reference circuit (Supply) and a common Sensor Ground. Each Signal circuit provides the Powertrain Control Module (PCM) with a signal voltage proportionate to throttle blade movement. Normally operating sensor signals are opposing to each other in the following manner:

- **TPS 1** voltage starts low, approximately 0.5 volts at **closed throttle,** and increases to approximately 4.5 volts at **wide open throttle** .
- **TPS 2** voltage starts high, approximately 4.3 volts at **closed throttle,** and decreases to approximately 0.7 volts at **wide open throttle** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- P2135 DTC is active.

SET CONDITION

- When fault P2135 is active, the Powertrain Control Module (PCM) looks at the difference between calculated Manifold Absolute Pressure (MAP) Sensor based on TPS 1 input and sensed MAP. The same is done for TPS 2. If the PCM determines that the TPS 1 error is larger than the TPS 2 error, this fault is set.

DEFAULT ACTION

- The MIL will illuminate.
- The ETC light will illuminate.

POSSIBLE CAUSES

Possible Causes
TPS 1 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
THROTTLE BODY ASSEMBLY
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

        Are there any applicable Service Bulletins or Flash updates?

        Yes

        - Perform the applicable repair.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

        Are there any Throttle Body circuit, system voltage or 5-Volt Reference DTCs present?

        Yes

        - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

        No

        - Go To 4

4. **ISOLATE AND CHECK THE THROTTLE BODY (K22) POSITION SIGNAL 1 CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

       Is the resistance below 3.0 Ohms?

       Yes

       - Go To 5

       No

       - Repair the circuit for an open or high resistance.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
5. **CHECK THE ABILITY OF THE PCM TO READ THE TPS 1 SIGNAL**
    1. Connect the PCM C2 harness connector.
    2. Connect a fused jumper between the Throttle Body (K22) Position Signal 1 circuit and the (F855) 5-Volt Supply circuit in the Throttle Body harness connector.
    3. Turn the ignition on.
    4. With the scan tool, read DTCs.

       NOTE: **The P0123-THROTTLE POSITION SENSOR 1 CIRCUIT HIGH DTC should be active or pending with the jumper in place.**

    5. Turn the ignition off.
    6. Connect a fused jumper between the Throttle Body (K22) Position Signal 1 circuit and the (K922) Sensor Ground circuit in the Throttle Body harness connector.
    7. Turn the ignition on.
    8. With the scan tool, read DTCs.

       NOTE: **The P0122-THROTTLE POSITION SENSOR 1 CIRCUIT LOW DTC should be active or pending with the jumper in place.**

       Does the scan tool display as described above?

Yes

- Replace the Throttle Body Assembly in accordance with the Service Information. Refer to **THROTTLE BODY, REMOVAL AND INSTALLATION** . After installation is complete, with scan tool perform an ETC Learn procedure to calibrate the Throttle Body Assembly.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Remove the jumper before continuing.
- Go To 6

6. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0122-THROTTLE POSITION SENSOR 1 CIRCUIT LOW

For a complete THROTTLE CONTROL SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Electronic Throttle Control (ETC) system uses two Throttle Position Sensors (TPS) to monitor the throttle blade position. TPS 1 and TPS 2 are located within the Throttle Body assembly. Each sensor has its own Signal circuit (TPS 1 or TPS 2). Both sensors share a common 5-Volt Reference circuit (Supply) and a common Sensor Ground. Each Signal circuit provides the Powertrain Control Module (PCM) with a signal voltage proportionate to throttle blade movement. Normally operating sensor signals are opposing to each other in the following manner:

- **TPS 1** voltage starts low, approximately 0.5 volts at **closed throttle,** and increases to approximately 4.5 volts at **wide open throttle** .
- **TPS 2** voltage starts high, approximately 4.3 volts at **closed throttle,** and decreases to approximately 0.7 volts at **wide open throttle** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the ignition on.
- Battery voltage greater than 10.4 volts.

SET CONDITION

- The TPS 1 Sensor input voltage is below 0.25 - 0.40 volts depending on calibration for 0.07 seconds.

DEFAULT ACTION

- The MIL will illuminate.
- The ETC light will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
TPS 1 SIGNAL CIRCUIT SHORTED TO GROUND
TPS 1 SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
THROTTLE BODY ASSEMBLY
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to **PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .**

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

Are there any applicable Service Bulletins or Flash updates?

Yes

- Perform the applicable repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read and record DTCs in all Electronic Control Units (ECUs) on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

        Are there any system voltage or 5-Volt Reference DTCs active or pending?

        Yes

        - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

        No

        - Go To 4
4. **ISOLATE AND CHECK THE THROTTLE BODY (K22) POSITION SIGNAL 1 CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Powertrain Control Module (PCM) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.

4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: There should be no continuity between ground and the circuit being tested.

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **ISOLATE AND CHECK THE THROTTLE BODY (K22) POSITION SIGNAL 1 CIRCUIT FOR A SHORT TO THE (K922) SENSOR GROUND CIRCUIT**
   1. The ignition must be off when checking for a short between circuits.
   2. Isolate the circuit by disconnecting the Powertrain Control Module (PCM) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: There should be no continuity between the circuits being tested.

Is there continuity between the circuits?

Yes

- Repair the short between the circuits.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK THE ABILITY OF THE PCM TO READ THE TPS 1 SIGNAL**
    1. The Powertrain Control Module (PCM) harness connectors must be connected to the PCM during this test step.
    2. Disconnect the sensor harness connector.
    3. With the ignition in the off position, connect a fused jumper between the sensor signal circuit and the 5-Volt Supply circuit at the sensor harness connector.
    4. Turn the ignition on.
    5. With the scan tool, read DTCs.

    Does the scan tool display the SENSOR SIGNAL CIRCUIT HIGH DTC with the jumper in place?

    Yes

    - Replace the faulty sensor in accordance with the Service Information. Refer to **THROTTLE BODY, REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 7
7. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
- Test complete.

P0123-THROTTLE POSITION SENSOR 1 CIRCUIT HIGH

For a complete THROTTLE CONTROL SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Electronic Throttle Control (ETC) system uses two Throttle Position Sensors (TPS) to monitor the throttle blade position. TPS 1 and TPS 2 are located within the Throttle Body assembly. Each sensor has its own Signal circuit (TPS 1 or TPS 2). Both sensors share a common 5-Volt Reference circuit (Supply) and a common Sensor Ground. Each Signal circuit provides the Powertrain Control Module (PCM) with a signal voltage proportionate to throttle blade movement. Normally operating sensor signals are opposing to each other in the following manner:

- **TPS 1** voltage starts low, approximately 0.5 volts at **closed throttle,** and increases to approximately 4.5 volts at **wide open throttle** .
- **TPS 2** voltage starts high, approximately 4.3 volts at **closed throttle,** and decreases to approximately 0.7 volts at **wide open throttle** .

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the ignition on.
- Battery voltage greater than 10.4 volts.

SET CONDITION

- The TPS input voltage is above 4.65 - 4.9 volts depending on calibration for 0.07 seconds.

DEFAULT ACTION

- The MIL will illuminate.
- ETC light will flash.
- The Throttle input and vehicle speed are limited.

POSSIBLE CAUSES

Possible Causes
5-VOLT SUPPLY CIRCUIT OPEN OR SHORTED TO GROUND
TPS 1 SIGNAL CIRCUIT SHORTED TO ANOTHER VOLTAGE SUPPLY CIRCUIT
TPS 1 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE

Possible Causes
THROTTLE BODY ASSEMBLY
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

       Are there any system voltage or 5-Volt Reference DTCs active or pending?

       Yes

       - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

No

- Go To 4

4. **CHECK THE (F855) 5-VOLT SUPPLY CIRCUIT FOR VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

    NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

    Is the voltage between 4.8 and 5.2 volts?

    Yes

    - Go To 5

    No

    - Repair the (F855) 5-Volt Supply circuit for an open or short to ground.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **CHECK THE THROTTLE BODY (K22) POSITION SIGNAL 1 CIRCUIT FOR A SHORT TO ANOTHER VOLTAGE SUPPLY CIRCUIT**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

        NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

        Is there continuity between the circuit being tested and any other circuit?

        Yes

        - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **ISOLATE AND CHECK THE THROTTLE BODY (K22) POSITION SIGNAL 1 CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 7

    No

    - Repair the circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **ISOLATE AND CHECK THE (K922) TPS SENSOR RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 8

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **CONNECT A FUSED JUMPER BETWEEN THE THROTTLE BODY (K22) POSITION SIGNAL 1 CIRCUIT AND THE (K922) SENSOR GROUND CIRCUIT AT THE THROTTLE BODY HARNESS CONNECTOR - VERIFY ABILITY OF THE PCM TO DETECT THE SENSOR SIGNAL CIRCUIT LOW DTC**
   1. The Electronic Control Module (ECU) harness connectors must be connected to the ECU during this test step.
   2. Disconnect the sensor harness connector.
   3. With the ignition in the off position, connect a fused jumper between the sensor signal circuit and the sensor ground circuit at the sensor harness connector.
   4. Turn the ignition on.
   5. With the scan tool, read DTCs.

   Does the scan tool display the SENSOR SIGNAL CIRCUIT LOW DTC with the jumper in place?

   Yes

   - Replace the faulty sensor in accordance with the Service Information. Refer to **THROTTLE BODY, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).

- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
- Test complete.

P0125-INSUFFICIENT COOLANT TEMP FOR CLOSED-LOOP FUEL CONTROL

THEORY OF OPERATION

The purpose of this diagnostic is to verify that the engine coolant temperature has reached a certain value (pass temperature) within a calibrated amount of engine run time. Engine run time is based on the start-up coolant temperature; the lower the start-up temperature, the more time allowed for the Engine Coolant Temperature (ECT) Sensor value to reach the pass temperature. If the engine coolant temperature does not reach the calibrated pass temperature before the engine run time reaches the maximum time allowed for this diagnostic, a failure will occur.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- At initial engine start up.
- With battery voltage greater than 10.4 volts.

SET CONDITION

- The engine temperature does not go above 10B°C (50B°F). Failure time depends on start-up coolant temperature and ambient temperature.
  - Up to two minutes for a start temp of 1B°C (33.8B°F) or above.

- Up to five minutes for a vehicle with a start-up temp between 0B°C and -29B°C (32B°F and -20.2B°F).
- Up to 10 minutes for a vehicle with a start-up temp of -30B°C (-22B°F) or below.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
LOW COOLANT LEVEL
THERMOSTAT
ENGINE COOLANT TEMPERATURE (ECT) SENSOR READING IRRATIONAL
RESTRICTION IN THE RADIATOR/COOLING SYSTEM
ENGINE COOLANT TEMPERATURE (ECT) SENSOR
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK THE COOLING SYSTEM FOR PROPER LEVEL AND CONDITION**

   WARNING: **Never open the cooling system when the engine is hot. The system is under pressure. Extreme burns or scalding may result. Failure to follow these instructions can result in possible serious or fatal injury. Allow the engine to cool before opening the cooling system.**

   1. Inspect the cooling system for proper level and condition.

      Is the coolant level and condition OK?

      Yes

      - Go To 2

      No

      - Inspect the vehicle for a coolant leak, make the appropriate repairs and add the correct amount of coolant. Refer to COOLING SYSTEM .
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .
2. **CHECK THE THERMOSTAT FOR PROPER OPERATION**

   NOTE: **For optimal test results, allow the vehicle to sit outside long enough to cool to ambient temperature in order to start the test with a totally cold soaked engine. With the scan tool, read the Engine Coolant Temperature degree value. If the engine was allowed to sit (cold soak), the temperature value should be a sensible value that is somewhere close to the ambient temperature.**

   1. Turn the ignition on.
   2. If engine coolant temperature is above 82B°C (180B°F), allow the engine to cool until it reaches at least 65B°C (150B°F) or cooler before continuing with this test.

3. Start the engine.
4. During engine warm-up monitor the Engine Coolant Temperature degree value on the scan tool. The temperature value change should be a smooth transition from start up to normal Thermostat opening temperature. Also monitor the actual coolant temperature with a digital thermometer at or near the ECT Sensor and Thermostat positions.

NOTE: **As the engine warms up to operating temperature, the actual coolant temperature (thermometer reading) and the scan tool Engine Coolant Temperature degree values should stay relatively close to each other. A discrepancy may indicate an inaccurate ECT Sensor signal to the PCM.**

5. As the engine warms to operating temperature, record the temperature at which the Thermostat opens.
6. Using the appropriate Service Information, determine the proper opening temperature of the thermostat.

   Did the thermostat open at the proper temperature?

   Yes

   - Go To 3

   No

   - Replace the Thermostat in accordance with the Service Information. Refer to **THERMOSTAT, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

3. **CHECK THE ECT SENSOR FOR PROPER OPERATION**

   Was the digital thermometer readings relatively close to the scan tool reading for the ECT Sensor during warm up and when the Thermostat opened?

   Yes

   - Go To 4

   No

   - Replace the Engine Coolant Temperature (ECT) Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE RADIATOR FOR RESTRICTIONS**

   NOTE: **The engine must be running and the Thermostat open to perform this test.**

   1. Check and compare the temperatures at the inlet and outlet of the Radiator. Check for proper operation of the entire cooling system. Be certain to check the Radiator Cap, flow through the Radiator and anything that can cause a lack of system pressure or lack of coolant flow in the system.

   NOTE: **It is normal to see a lower temperature on the outlet of the Radiator, however a very large difference indicates a restriction in the Radiator core. This can cause this DTC to set due to the position on the ETC**

Sensor in the system. If necessary, compare the temperature difference with a similar vehicle.

Was the difference in the temperature readings relatively larger than expected?

Yes

- Replace the Radiator in accordance with the Service Information. Refer to **RADIATOR, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. With the scan tool, erase DTCs.
    9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    10. With the scan tool, read DTCs.

       Did the DTC return?

       Yes

       - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0128-THERMOSTAT RATIONALITY

THEORY OF OPERATION

The Thermostat is considered malfunctioning if the coolant temperature does not reach the temperature required to enable other diagnostics, or the coolant temperature does not reach a warmed up temperature within 11.0B°C (20B°F) of the Thermostat regulating temperature. The Powertrain Control Module (PCM) creates a model of the engine coolant temperature warm up cycle, based on the engine coolant temperature at start up, ambient temperature, vehicle speed and engine speed. The modeled engine coolant temperature is compared to the Engine Coolant Temperature (ECT) Sensor reading. If the engine actual temperature reaches the calibrated temperature threshold before the model, the diagnostic passes and completes.

If the model reaches the calibrated temperature threshold before the engine actual temperature, a pass/fail determination is made based on the difference between the model and actual values. The diagnostic is considered passing if the difference between the engine actual temperature and model is acceptable when the model is greater than the engine but represents the slowest possible warm-up for a "good" thermostat.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- With the engine running.
- Start up coolant temperature less than 65B°C (149B°F).
- Ambient temperature between -8B°C (17.6B°F) and 50B°C (122B°F).
- Average vehicle speed greater than 16 km/h (10 mph) until coolant temperature reaches 85B°C.
- Engine speed does not go above 5400 rpm for more than 32 seconds.
- The pass/fail determination point is reached when the coolant temp model reaches 88B°C (190.4B°F).

SET CONDITION

- The predicted coolant temperature reaches the target threshold before the actual coolant temperature and the PCM detects that the actual engine coolant temperature is too far below what is acceptable for a good thermostat.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
LOW COOLANT LEVEL
COOLING SYSTEM ISSUES - POOR FLOW DUE TO A RESTRICTION OR MECHANICAL ISSUE
FAULTY THERMOSTAT - OPENING TOO SOON

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR OTHER DTCS**
    1. Turn the ignition on.

2. With the scan tool, read and record DTCs.

   Are there any ECT or AAT DTCs active or pending?

   Yes

   - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

   No

   - Go To 2

2. **CHECK THE COOLANT LEVEL AND CONDITION**

WARNING: **Never open the cooling system when the engine is hot. The system is under pressure. Extreme burns or scalding may result. Failure to follow these instructions can result in possible serious or fatal injury. Allow the engine to cool before opening the cooling system.**

1. Inspect the Engine Coolant for proper level and condition. Refer to **COOLING SYSTEM** .

   Is the Engine Coolant at the proper level and condition?

   Yes

   - Go To 3

   No

   - Repair the Engine Coolant level or condition problem. Inspect the vehicle for coolant leaks and repair if necessary. Fill the Engine Coolant to the proper level and ensure the proper condition. Refer to **COOLING SYSTEM** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

3. **CHECK THE THERMOSTAT OPERATION**

NOTE: **For optimal test results, allow the vehicle to sit outside long enough to cool to ambient temperature in order to start the test with a totally cold soaked engine. With the scan tool, read the Engine Coolant Temperature degree value. If the engine was allowed to sit (cold soak), the temperature value should be a sensible value that is somewhere close to the ambient temperature.**

1. Turn the ignition on.
2. If engine coolant temperature is above 82B°C (180B°F), allow the engine to cool until it reaches at least 65B°C (150B°F) or cooler before continuing with this test.
3. Start the engine.
4. During engine warm-up monitor the Engine Coolant Temperature degree value on the scan tool. The temperature value change should be a smooth transition from start up to Thermostat opening temperature. Also monitor the actual coolant temperature with a digital thermometer at or near the ECT Sensor and Thermostat positions.

   NOTE: **As the engine warms up to operating temperature, the actual coolant temperature (thermometer reading) and the scan tool Engine Coolant Temperature degree values should stay relatively close to each other. A discrepancy may indicate an inaccurate ECT Sensor signal to the PCM.**

5. As the engine warms to operating temperature, record the temperature at which the Thermostat opens.
6. Using the appropriate Service Information, determine the proper opening temperature of the Thermostat.

Did the Thermostat open at the proper temperature?

Yes

- Go To 4

No

- Replace the Thermostat in accordance with the Service Information. Refer to **THERMOSTAT, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE RADIATOR FOR RESTRICTIONS AND FLOW**

NOTE: **The engine must be running and the Thermostat open to perform this test.**

1. Check and compare the temperatures at the inlet and outlet of the Radiator. Check for proper operation of the entire cooling system. Be certain to check for proper operation of the Radiator Cap. Check for proper flow through the Radiator and anything that can cause a lack of system pressure or lack of coolant flow in the system which include air in the cooling system, proper operation of the Water Pump and drive belt, restricted Radiator core, collapsed hose restricting flow, etc.

NOTE: **It is normal to see a lower temperature on the outlet of the Radiator, however a very large difference could indicate a restriction in the Radiator. This condition can cause this DTC to set due to the position of the ETC Sensor in the coolant system. If necessary, compare the temperature difference with a similar vehicle.**

Was the difference in the temperature readings relatively larger than expected?

Yes

- Check the cooling system and Radiator for proper flow and repair as necessary.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Replace the Thermostat in accordance with the Service Information. Refer to **THERMOSTAT, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0129-BAROMETRIC PRESSURE OUT OF RANGE LOW

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Powertrain Control Module (PCM) runs a diagnostic to check the Manifold Absolute Pressure Sensor (MAP) calibration and 5-Volt Supply circuit. It does this by reading the Barometric Pressure (BARO) when the engine is not running. The BARO reading with the engine off should fall within a predictable threshold. If the reading is below this threshold when the monitoring conditions are met, it is determined that the 5-Volt Supply was lost or the MAP Sensor is out of range.

NOTE: **Do not use shop air to clean out the MAP Sensor when diagnosing a MAP Sensor related fault as this will cause internal damage to the sensor.**

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- With the ignition on.
- After an engine off period of 12.0 seconds.
- Battery voltage greater than 10.4 volts.
- Engine speed less than 30 rpm.

SET CONDITION

- The voltage from the MAP Sensor is less than 2.28 volts, but above 0.10 volts.

DEFAULT ACTION

- ETC light will flash.
- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
5-VOLT SUPPLY CIRCUIT OPEN
MANIFOLD ABSOLUTE PRESSURE (MAP) SENSOR

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

    No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

NOTE: **Diagnose and repair any 5-Volt Reference DTCs before continuing with this test procedure.**

2. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT FOR PROPER VOLTAGE AT THE MAP SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

NOTE: **Normal operating voltage should be between 4.8 and 5.2 volts.**

Does the circuit have the proper voltage present?

Yes

- Verify that there is good pin to terminal contact in the MAP Sensor and Powertrain Control Module connectors. If no problems are found, replace the MAP Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Repair the (F856) 5-Volt Supply circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0131-O2 SENSOR 1/1 CIRCUIT LOW

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other

	Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.**
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading

Using the Scan Tool for Diagnostics:	
	will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Battery voltage between 11.0 and 15.75 volts.
- With the engine running.

SET CONDITION

- The Oxygen Sensor 1/1 signal voltage is less than 0.0 volts for 9.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/1 SIGNAL CIRCUIT SHORTED TO GROUND

Possible Causes
O2 SENSOR 1/1 SIGNAL CIRCUIT SHORTED TO THE O2 SENSOR 1/1 HEATER GROUND CIRCUIT
O2 SENSOR 1/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.

4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, (special tool #10436, Adapter, GPEC Diagnostic) connect the to the appropriate PCM harness connector.

   NOTE: There should be no continuity between ground and the circuit being tested.

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 4

4. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR A SHORT TO THE (Z910) GROUND CIRCUIT**
   1. The ignition must be off when checking for a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: There should be no continuity between the circuits being tested.

   Is there continuity between the circuits?

   Yes

   - Repair the short between the circuits.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5

5. **CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

    Is the O2 Sensor 1/1 voltage above 4.0 volts?

    Yes

    - Replace the O2 Sensor 1/1 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 6
6. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.

11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information.. **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0132-O2 SENSOR 1/1 CIRCUIT HIGH

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within

the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50**

	percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will

Using the Scan Tool for Diagnostics:	
(Return) Circuit Low Diagnosis:	switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Battery voltage between 11.0 and 15.75 volts.
- With the engine running.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Oxygen Sensor 1/1 (0-1) differential signal voltage is above 1.2 volts for over 9.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/1 HEATER CONTROL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 1/1 HEATER CONTROL CIRCUIT SHORTED TO GROUND
O2 SENSOR 1/1 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/1 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/1 SIGNAL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 1/1 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/1 RETURN CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
    1. Start the engine and allow it to idle for at least 60 seconds.

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

2. With the scan tool, read the O2 Sensor 1/1 signal voltage.

   Is the voltage staying above 4.0 volts?

   Yes

   - Go To 2

   No

   - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK THE O2 SENSOR 1/1 HEATER OPERATION**
   1. With the scan tool, check the O2 Sensor 1/1 duty cycle. Also monitor the O2 Sensor 1/1 heater temperature and compare to the other O2 Sensor heater temperatures.

   NOTE: **The duty cycle percentage and heater temperature should be relatively close to the other sensors. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably different than the other O2 Sensors.**

   Is the O2 Sensor heater operating properly?

   Yes

   - Go To 7

   No

   - Go To 3

3. **CHECK THE O2 SENSOR 1/1 (Z910) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
   1. Disconnect the component harness connector to isolate the ground circuit.
   2. Connect the positive lead of the load test tool to the positive side of the Battery.
   3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
   4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

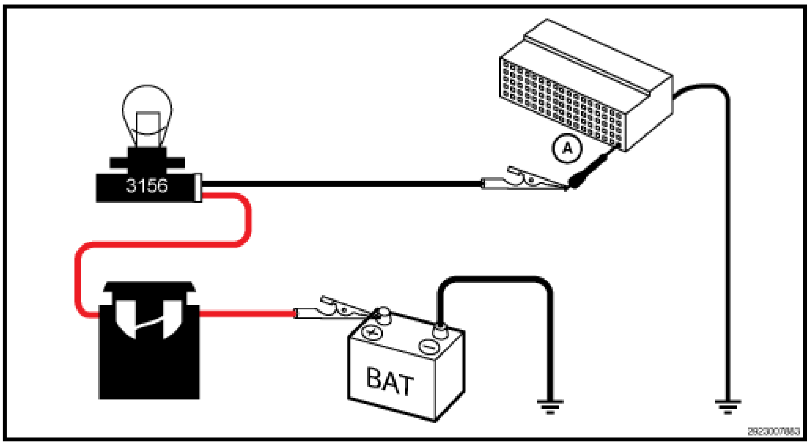
NOTE: **Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.

   NOTE: Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.

   Is the load test bulb illuminated and bright?

Yes

- Go To 4

No

- Repair the ground circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K99) HEATER CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

    Is there continuity between the circuit being tested and any other circuit?

    Yes

    - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 5

5. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K99) HEATER CONTROL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to**

pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

No

- Go To 6

6. **ISOLATE AND LOAD TEST THE O2 SENSOR 1/1 (K99) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
    1. The ignition must be off when performing a load test on a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
    3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
    4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at one of the component harness connectors (B).
    5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
    6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

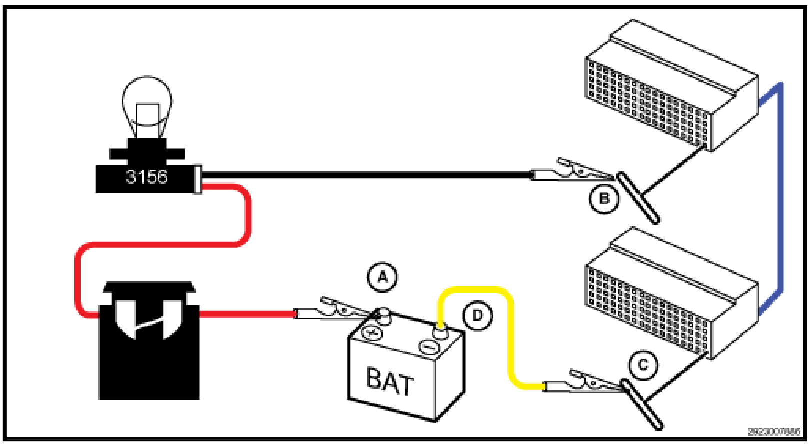
NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage**

drop test across the 3156 bulb of the load test tool. To do so perform the following:

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 10

   No

   - Repair the circuit for an open or high resistance.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

    NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

    Is the voltage above 5.2 volts?

    Yes

    - Repair the circuit for a short to voltage.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 8

8. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

        NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

        Is the resistance below 3.0 Ohms?

        Yes

        - Go To 9

        No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

9. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K902) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 10

    No

    - Repair the circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **REPLACE THE O2 SENSOR 1/1 AND RETEST FOR DTC**
    1. Replace the O2 Sensor 1/1 in accordance with the Service Information. Refer to **THROTTLE BODY, REMOVAL AND INSTALLATION** .
    2. Connect the O2 Sensor 1/1 and PCM harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs.
    5. Using the recorded Freeze Frame and the When Monitored conditions, operate the vehicle in the conditions that set the DTC.
    6. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 11

    No

    - Replacing the O2 Sensor repaired the fault.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
       - Proper connector installation.
       - Damaged connector locks.
       - Corrosion.
       - Other signs of water intrusion.
       - Weather seal damage (if equipped).
       - Bent terminals.
       - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
       - Terminals that have been pushed back into the connector cavity.
       - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0133-O2 SENSOR 1/1 SLOW RESPONSE

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Upstream Oxygen (O2) Sensor is usually placed close to the exhaust manifold to achieve fast light-off and provide immediate O2 feedback to allow the fuel system to enter closed loop fuel control.

The Upstream O2 Sensor is very important for emission control and engine performance since it can provide immediate air/fuel ratio feedback. Therefore, proper operation of this Upstream O2 Sensor is critical. An aged Upstream O2 Sensor tends to be less active and has a slower response rate to changes in the air/fuel ratio of exhaust gas. As a result, the quality of the Upstream O2 Sensor can be determined by observing the voltage activity from the sensor.

This monitor is triggered when the engine is running at certain MAP/RPM windows, airflow is relatively stable and steady O2 control is applied. The state change for Upstream O2 signal is captured in a calibrated time block (consisting of consecutive samples), such that even the slowest (but still considered as passing) O2 Sensor should accumulate enough state changes to pass the monitor.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Engine Coolant Temperature (ECT) Sensor value above 70B°C (158B°F).
- Engine speed between 1400 and 2300 rpm.
- Vehicle speed between 64 and 96 km/h (40 and 60 mph).
- Engine run time greater than three minutes.

SET CONDITION

- PCM detects that the oxygen sensor signal does not switch adequately during monitoring.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
EXHAUST LEAK
O2 SENSOR 1/1 SIGNAL CIRCUIT
O2 SENSOR 1/1 RETURN CIRCUIT
OXYGEN (O2) SENSOR 1/1

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.

6. Using the When Monitored Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECKING THE EXHAUST SYSTEM FOR LEAKS**
    1. Perform the CHECKING THE EXHAUST SYSTEM FOR LEAKS test procedure. Refer to **CHECKING THE EXHAUST SYSTEM FOR LEAKS** .

    Were any exhaust leaks found?

    Yes

    - Repair or replace the leaking exhaust parts as necessary.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 3

3. **CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **Normal operating voltage should be between 4.1 and 5.0 volts.**

Does the circuit have the proper voltage present?

Yes

- Go To 8

No

- Go To 4

4. **CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

Is the voltage above 5.2 volts?

Yes

- Go To 5

No

- Go To 6

5. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

    Is there continuity between the circuit being tested and any other circuit?

    Yes

    - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 14

6. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.

2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
3. Connect the negative lead of the DVOM to a known good ground.
4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 7

7. **ISOLATE AND CHECK THE O2 SENSOR 1/1 (K41) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 13

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **CHECK THE (K902) SENSOR RETURN CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    NOTE: **Normal operating voltage should be approximately 2.5 volts.**

    Does the circuit have the proper voltage present?

    Yes

    - Go To 13

    No

    - Go To 9

9. **CHECK THE (K902) SENSOR RETURN CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

    NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

    Is the voltage above 5.2 volts?

    Yes

    - Go To 10

    No

    - Go To 11

10. **ISOLATE AND CHECK THE (K902) SENSOR RETURN CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

    Is there continuity between the circuit being tested and any other circuit?

    Yes

    - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 14
11. **ISOLATE AND CHECK THE (K902) SENSOR RETURN CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    NOTE: **There should be no continuity between ground and the circuit being tested.**

    Is there continuity between ground and the circuit being tested?

    Yes

    - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 12

12. **ISOLATE AND CHECK THE (K902) SENSOR RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    Is the resistance below 3.0 Ohms?

    Yes

    - Repair the (K902) Sensor Return circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 13

13. **CHECK THE O2 SENSOR 1/1 WIRING AND CONNECTOR**

    NOTE: **Check for signs of contaminants that may have damaged the O2 Sensor, such as contaminated fuel, unapproved silicone, oil and coolant.**

    1. Using the wiring diagram/schematic as a guide, inspect the wiring and connectors between the O2 Sensor 1/1 and the Powertrain Control Module (PCM).
        - Look for any chafed, pierced, pinched, or partially broken wires.
        - Look for broken, bent, pushed out or corroded terminals.
        - Verify that there is good pin to terminal contact in the 1/1 O2 Sensor and Powertrain Control Module connectors.
        - Perform any Service Bulletins that may apply.

    Were any problems found?

    Yes

    - Repair as necessary.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Replace the O2 Sensor 1/1 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace the Powertrain Control Module (PCM) in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

- Test complete.

P0135-O2 SENSOR 1/1 HEATER PERFORMANCE

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The primary objective of the Oxygen (O2) Sensor Heater Control is to attain the fastest possible temperature rise, and to control the steady state temperature of the O2 Sensor. A Positive Temperature Coefficient (PTC) element inside the O2 Sensor heats up as current passes through it. This allows the system to enter Closed Loop quickly and meet the OBD II requirements for continuous monitoring and to deliver accurate readings. This is accomplished by the Powertrain Control Module (PCM) sending a Pulse Width Modulated (PWM) current to the O2 Sensors heater element. The PWM duty cycle is calculated, in response to the temperature measurements. The PCM uses the collected information to continually adjust the PWM to achieve a desired steady state temperature target.

The heater temperature is obtained by measuring the heater resistance and calculating the heater temperature using the resistance versus temperature characteristic. In order to measure the heater temperature, the transistor that controls the heater is momentarily disabled and current is passed through a precision sense resistor connected in series with the heater element. The voltage drop across the sense resistor provides the relationship to current which equates to a temperature value. Once the temperature is acquired, the sense current is turned off and normal operation is restored. The actual heater temperature is monitored continuously and the heating rate is adjusted to prevent damaging the heating element.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage between 11.0 and 15.75 volts.
- No Ambient Air Temperature Sensor faults set.
- And any one of the following is true:
  - Engine coolant temperature at start up is above 7B°C (44.6B°F).
  - Ambient temperature is above 7B°C (44.6B°F).
  - The difference between coolant temperature and ambient temperature is greater than 9B°C (16.2B°F) at engine start.
  - The O2 Sensor heater temperature is greater than 401B°C (753.8B°F) for more than 20.0 seconds.

SET CONDITION

- The PCM detects that the difference between the actual O2 Sensor Heater element resistance/temperature and the target resistance/temperature is not within a calibrated threshold with the O2 Sensor heater duty cycle above 89.8% for 90.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/1 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/1 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
OXYGEN (O2) SENSOR 1/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **CHECK FOR AN ACTIVE CONDITION**
    1. Turn the ignition off.

       NOTE: **Wait a minimum of eight minutes to allow the sensor to cool down before continuing. The sensor voltage should stabilize between 2.47 and 2.52 volts.**

    2. Turn the ignition on.
    3. With a scan tool, actuate the O2 Sensor 1/1 heater control.
    4. With the scan tool, monitor the O2 Sensor 1/1 voltage for at least two minutes.

       Does the voltage stay above approximately 4.5 volts?

       Yes

       - Go To 3

       No

       - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **CHECK FOR OTHER DTCS**
    1. With the scan tool, read and record DTCs on the repair order.

       Are there any other O2 Sensor Heater circuit DTCs active or pending?

       Yes

       - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 4
4. **CHECK THE O2 SENSOR 1/1 HEATER ELEMENT RESISTANCE**
    1. Turn the ignition off.

NOTE: **Allow the O2 Sensor heater a few minutes to cool down from the heater test performed with the scan tool.**

2. Disconnect the O2 Sensor 1/1 harness connector.
3. Measure the resistance of the O2 Sensor 1/1 Heater Element across the O2 Sensor, between the O2 Heater Control terminal and the Heater ground terminal (component side).

NOTE: **If possible, it's best to measure the O2 Sensor 1/1 Heater Element resistance value at approximately 20B°C (68B°F). The resistance value will vary with different temperature values. If the O2 Sensor is obviously warmer or cooler than the recommended temperature, use the table below to estimate what the resistance range should be. The MAXIMUM allowable resistance would be 12.5 Ohms at 1000B°C.**

Celsius	Fahrenheit	Resistance Range
0B°C	32B°F	3.1 - 4.2 Ohms
20B°C	68B°F	3.3 - 4.4 Ohms
100B°C	212B°F	3.85 - 5.1 Ohms

Is the O2 Sensor resistance within the acceptable range?

Yes

- Go To 5

No

- Verify that there is good pin to terminal contact in the O2 Sensor and PCM harness connectors. If no problems are found, replace the O2 Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **ISOLATE AND LOAD TEST THE O2 SENSOR 1/1 (K99) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
   1. The ignition must be off when performing a load test on a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
   3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
   4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
   5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
   6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load**

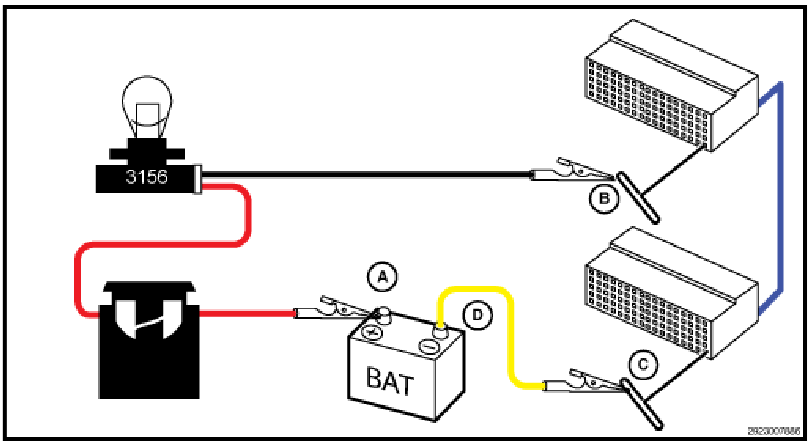
testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .

NOTE: Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

- 1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
- 2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
- 3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.

CAUTION: Do not load test any circuits with components still connected to the circuit.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to

pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

NOTE: **There should be no continuity between ground and the circuit being tested.**

NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

Is the load test bulb illuminated and bright?

Yes

- Go To 6

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **ISOLATE AND LOAD TEST THE (Z910) GROUND CIRCUIT TO CHECK FOR HIGH RESISTANCE**
   1. The ignition must be off when performing a load test on a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
   3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
   4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
   5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
   6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

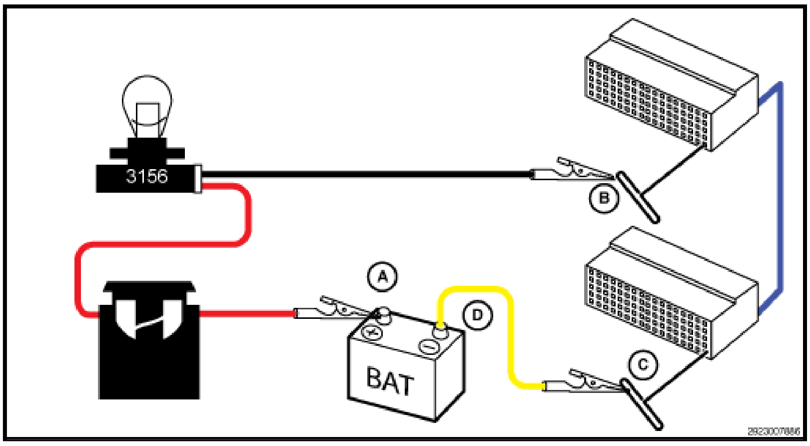
NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load**

test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

- 1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
- 2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
- 3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.

CAUTION: Do not load test any circuits with components still connected to the circuit.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: There should be no continuity between ground and the circuit being tested.

NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

Is the load test bulb illuminated and bright?

Yes

- Go To 7

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **CHECK RELATED HARNESS CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. With the scan tool, erase DTCs.
    9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0137-O2 SENSOR 1/2 CIRCUIT LOW

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the**

Using the Scan Tool for Diagnostics:	
	O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the

Using the Scan Tool for Diagnostics:	
(Return) Circuit High Diagnosis:	signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Battery voltage between 11.0 and 15.75 volts.
- With the engine running.

SET CONDITION

- The Oxygen Sensor 1/2 signal voltage is less than 0.0 volts for 9.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/2 SIGNAL CIRCUIT SHORTED TO GROUND
O2 SENSOR 1/2 SIGNAL CIRCUIT SHORTED TO THE O2 SENSOR 1/2 HEATER GROUND CIRCUIT
O2 SENSOR 1/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.

3. With the scan tool, erase all DTCs.
4. Turn the ignition off for a minimum of 10.0 seconds.
5. Turn the ignition on.
6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 3

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **ISOLATE AND CHECK THE O2 SENSOR 1/2 (K141) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, (special tool #10436, Adapter, GPEC Diagnostic) connect the to the appropriate PCM harness connector.

    NOTE: **There should be no continuity between ground and the circuit being tested.**

    Is there continuity between ground and the circuit being tested?

    Yes

    - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 4

4. **ISOLATE AND CHECK THE O2 SENSOR 1/2 (K141) SIGNAL CIRCUIT FOR A SHORT TO THE (Z910) GROUND CIRCUIT**
    1. The ignition must be off when checking for a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as

a guide to follow the path of the circuit.

3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: There should be no continuity between the circuits being tested.

   Is there continuity between the circuits?

   Yes

   - Repair the short between the circuits.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5

5. **CHECK THE O2 SENSOR 1/2 (K141) SIGNAL CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
   1. Turn the ignition off.
   2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
   3. Turn the ignition on.
   4. Set the DVOM to measure DC voltage.
   5. Connect the negative lead of the DVOM to a known good ground.
   6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

   Is the O2 Sensor 1/2 voltage above 4.0 volts?

   Yes

   - Replace the O2 Sensor 1/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 6

6. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.

5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
    - Proper connector installation.
    - Damaged connector locks.
    - Corrosion.
    - Other signs of water intrusion.
    - Weather seal damage (if equipped).
    - Bent terminals.
    - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
    - Terminals that have been pushed back into the connector cavity.
    - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0138-O2 SENSOR 1/2 CIRCUIT HIGH

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A**

small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set. Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool.

NOTE:

When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably

	higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage between 11.0 volts and 15.8 volts.

SET CONDITION

- The PCM detects that Oxygen Sensor 1/2 signal voltage is greater than 1.20 volts.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/2 HEATER CONTROL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 1/2 HEATER CONTROL CIRCUIT SHORTED TO GROUND
O2 SENSOR 1/2 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/2 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/2 SIGNAL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 1/2 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/2 RETURN CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
    1. Start the engine and allow it to idle for at least 60 seconds.

       WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    2. With the scan tool, read the O2 Sensor 1/2 signal voltage.

       Is the voltage staying above 4.0 volts?

       Yes

       - Go To 2

       No

       - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to INTERMITTENT CONDITION .
2. **CHECK THE O2 SENSOR 1/2 HEATER OPERATION**
    1. With the scan tool, check the O2 Sensor 1/2 duty cycle. Also monitor the O2 Sensor 1/2 heater temperature and compare to the other O2 Sensor heater temperatures.

       NOTE: **The duty cycle percentage and heater temperature should be relatively close to the other sensors. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably different than the other O2 Sensors.**

       Is the O2 Sensor heater operating properly?

       Yes

       - Go To 7

No

- Go To 3

3. **CHECK THE O2 SENSOR 1/2 (Z910) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
    1. Disconnect the component harness connector to isolate the ground circuit.
    2. Connect the positive lead of the load test tool to the positive side of the Battery.
    3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
    4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

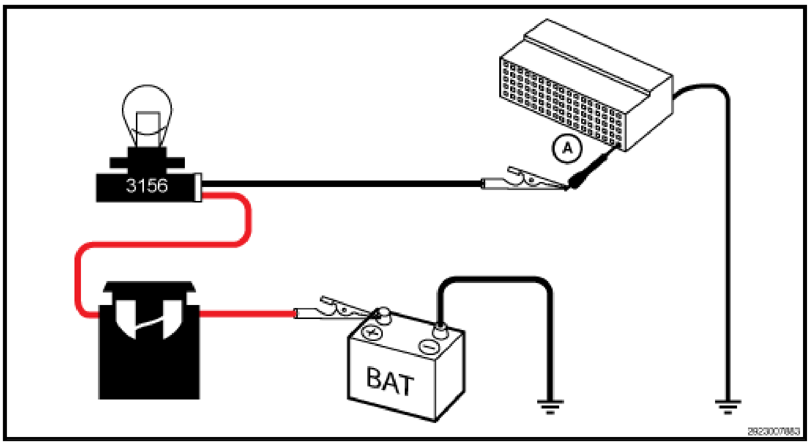
NOTE: **Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 4

   No

   - Repair the ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND CHECK THE O2 SENSOR 1/2 (K299) HEATER CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
   4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **ISOLATE AND CHECK THE O2 SENSOR 1/2 (K299) HEATER CONTROL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **ISOLATE AND LOAD TEST THE O2 SENSOR 1/2 (K299) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
    1. The ignition must be off when performing a load test on a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.

3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at one of the component harness connectors (B).
5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

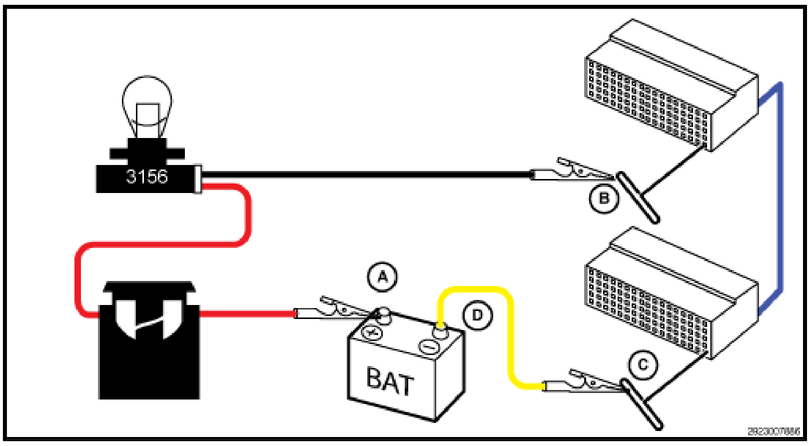
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

Is the load test bulb illuminated and bright?

Yes

- Go To 10

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **CHECK THE O2 SENSOR 1/2 (K141) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
   1. Turn the ignition off.
   2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Turn the ignition on.
   4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

Is the voltage above 5.2 volts?

Yes

- Repair the O2 Sensor 1/2 (K141) Signal circuit for a short to voltage.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 8

8. **ISOLATE AND CHECK THE O2 SENSOR 1/2 (K141) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

   CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

      NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 9

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

9. **ISOLATE AND CHECK THE O2 SENSOR 1/2 (K904) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

   CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 10

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **REPLACE THE O2 SENSOR 1/2 AND RETEST FOR DTC**
    1. Replace the O2 Sensor 1/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    2. Connect the O2 Sensor 1/2 and PCM harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs.
    5. Using the recorded Freeze Frame and the When Monitored conditions, operate the vehicle in the conditions that set the DTC.
    6. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 11

    No

    - Replacing the O2 Sensor repaired the fault.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
11. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
       - Proper connector installation.
       - Damaged connector locks.
       - Corrosion.
       - Other signs of water intrusion.
       - Weather seal damage (if equipped).
       - Bent terminals.
       - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
       - Terminals that have been pushed back into the connector cavity.
       - Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0139-O2 SENSOR 1/2 SLOW RESPONSE

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

For an aged Oxygen (O2) Sensor, the response rate to the air/fuel change is slower than when it was new. The O2 Sensor tends to move less with the same air/fuel changes in a given time frame. Therefore by observing the activity of voltage readings from the O2 Sensor, the quality of the O2 Sensor can be detected.

The Downstream O2 Sensor is located in the exhaust path behind the Catalytic Converter, and is monitored for proper response to assure optimum Catalytic Converter efficiency. This occurs by monitoring the change in the Downstream O2 Sensor voltage over time, when the fuel is shut off during a decel condition after the enable conditions were met. If the slope of the Downstream O2 Sensor is too small, the monitor will fail indicating that the O2 Sensor is not reliable enough to monitor Catalytic Converter efficiency.

WHEN MONITORED

This diagnostic runs during a decel fuel shutoff event, after the following conditions were met:

- Vehicle speed above 96 km/h (60 mph).
- Throttle open for a minimum of 120 seconds.
- Coolant temperature greater than 70B°C (158B°F).
- Catalytic Converter temperature greater than 600B°C (1112B°F).

SET CONDITION

- If the PCM does not detect a rich to lean switch within a specific time during a Decel Fuel Shutoff Event, the monitor will fail.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
RESTRICTED INTAKE AIR FLOW (PLUGGED AIR FILTER)
LEAK IN THE EXHAUST SYSTEM
UPSTREAM AND DOWNSTREAM O2 SENSOR HARNESS CONNECTORS SWITCHED
O2 SENSOR 1/2 INSTALLED INCORRECTLY
O2 SENSOR 1/2
ENGINE MECHANICAL ISSUE CAUSING O2 SENSOR CONTAMINATION
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

       Did the DTC return?

       Yes

       - Go To 2

       No

       - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

- Go To 3

3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

    NOTE: **Any O2 Sensor heater or signal circuit DTCs should be diagnosed before continuing with this procedure.**

    Are there any O2 Sensor heater or signal circuit DTCs present?

    Yes

    - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

    No

    - Go To 4

4. **CHECK THE INTAKE SYSTEM AND AIR FILTER FOR RESTRICTIONS OR BLOCKAGE**
    1. Check for a blockage in the intake air system plumbing.
    2. Visually inspect the Air Filter for a restriction.

    NOTE: **Poor airflow due to a severely restricted Air Filter can cause this DTC to set.**

    Were any issues found?

    Yes

    - Replace the Air Filter or repair the blockage.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 5

5. **CHECK THE O2 SENSOR FOR PROPER MOUNTING**
    1. Check and verify that the Upstream O2 Sensor is mounted correctly into the exhaust. Verify the sensor is tight and not cross threaded.

    Is the O2 Sensor mounted correctly?

    Yes

    - Go To 6

    No

    - Mount the O2 Sensor correctly.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE ORIENTATION OF THE UPSTREAM AND DOWNSTREAM O2 SENSOR HARNESS CONNECTORS**
    1. Check and verify that the Upstream O2 Sensor and Downstream O2 Sensor harness connectors are properly connected to the correct sensors.

    Are the harness connectors reversed?

Yes

- Connect the harness connectors to the correct sensors.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 7

7. **CHECK THE EXHAUST SYSTEM FOR LEAKS**
    1. Perform the CHECKING THE EXHAUST SYSTEM FOR LEAKS test procedure. Refer to **CHECKING THE EXHAUST SYSTEM FOR LEAKS** .

    Were any exhaust leaks found?

    Yes

    - Repair or replace the leaking exhaust parts as necessary.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 8

8. **REPLACE THE O2 SENSOR 1/2 AND RETEST FOR DTC**

    NOTE: **Check for signs of contaminants that may have damaged the O2 Sensor, such as contaminated fuel, unapproved silicone, oil and coolant.**

    1. Replace the O2 Sensor 1/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    2. Connect the O2 Sensor 1/2 and PCM harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs.
    5. Using the recorded Freeze Frame and the When Monitored conditions, operate the vehicle in the conditions that set the DTC.
    6. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 9

    No

    - Replacing the O2 Sensor 1/2 repaired the fault. If the O2 Sensor was contaminated, also correct the engine mechanical condition that caused the contamination on the sensor.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.

5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
    - Proper connector installation.
    - Damaged connector locks.
    - Corrosion.
    - Other signs of water intrusion.
    - Weather seal damage (if equipped).
    - Bent terminals.
    - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
    - Terminals that have been pushed back into the connector cavity.
    - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0140-O2 SENSOR 1/2 NO ACTIVITY DETECTED

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Downstream Oxygen (O2) Sensor no activity diagnostic monitor is intended to diagnose a Downstream O2 Sensor that is not moving or is stuck in a voltage window. This diagnostic is intended to verify the Downstream O2 Sensors ability to respond to fuel adaption deviations during the Catalyst Monitor test. To pass this monitor, the sensor must output a voltage greater than a high calibrated voltage and less than a low calibrated voltage within a calibrated time period. The test includes a non-intrusive monitor and an intrusive fueling monitor. The intrusive monitor will only run if the non-intrusive test does not pass within the calibrated time period.

The intrusive fueling routine is used to 'jolt' the fuel feedback system to force the monitor to pass. A test failure occurs if the voltage pass values are not achieved after the total accumulated test time.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- With the engine running.
- Vehicle speed between 32 and 88 km/h (20 and 55 mph).
- Throttle open for a minimum of 120 seconds.
- Engine Coolant Temperature (ECT) Sensor value greater than 70B°C (158B°F).
- Catalytic Converter Temperature greater than 600B°C (1112B°F).
- EVAP Purge active.

SET CONDITION

- The Oxygen Sensor 1/2 signal switches from lean to rich less than 16 times within 20 seconds during monitoring.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
EXHAUST LEAK
O2 SENSOR 1/2 SIGNAL CIRCUIT
O2 SENSOR 1/2 RETURN CIRCUIT
OXYGEN (O2) SENSOR 1/2

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

    No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECKING THE EXHAUST SYSTEM FOR LEAKS**
    1. Perform the CHECKING THE EXHAUST SYSTEM FOR LEAKS test procedure. Refer to **CHECKING THE EXHAUST SYSTEM FOR LEAKS** .

       Were any exhaust leaks found?

       Yes

       - Perform the appropriate repairs.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 3

3. **CHECK THE O2 SENSOR 1/2 (K141) SIGNAL CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR 1/2 SIGNAL HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **Normal operating voltage should be between 4.1 and 5.0 volts.**

   Does the circuit have the proper voltage present?

   Yes

   - Go To 4

   No

   - Check the O2 Sensor 1/2 (K141) Signal circuit for a short to ground, open or short to voltage. If no problems are found, replace and program the PCM in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE (K904) SENSOR RETURN CIRCUIT FOR PROPER VOLTAGE AT THE O2 1/2 SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.

2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
3. Turn the ignition on.
4. Set the DVOM to measure DC voltage.
5. Connect the negative lead of the DVOM to a known good ground.
6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **Is the voltage at 2.5 volts?**

   Does the circuit have the proper voltage present?

   Yes

   - Go To 5

   No

   - Check the (K904) Sensor Return circuit for a short to ground, open or short to voltage. If no problems are found, replace and program the PCM in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **CHECK THE OXYGEN SENSOR FOR PROPER OPERATION**

NOTE: **Check for signs of contaminants that may have damaged the O2 Sensor 1/2, such as contaminated fuel, unapproved silicone, oil and coolant.**

1. Using the wiring diagram/schematic as a guide, inspect the wiring and connectors between the O2 Sensor 1/2 and the Powertrain Control Module (PCM).
2. Look for any chafed, pierced, pinched or partially broken wires.
3. Look for broken, bent, pushed out or corroded terminals.
4. Perform any Service Bulletins that may apply.

   Were any problems found?

   Yes

   - Repair as necessary.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Replace the Oxygen Sensor 1/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0141-O2 SENSOR 1/2 HEATER PERFORMANCE

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.

- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the**

	heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the

Using the Scan Tool for Diagnostics:	
	(0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- With the engine running.
- Battery voltage between 11.0 and 15.75 volts.
- No Ambient Air Temperature Sensor faults set.
- And any one of the following is true:
  - Engine coolant temperature at start up is above 7B°C (44.6B°F).
  - Ambient temperature is above 7B°C (44.6B°F).
  - The difference between engine coolant temperature and ambient temperature is greater than 9B°C (16.2B°F) at engine start.
  - The O2 Sensor heater temperature is greater than 401B°C (753.8B°F) for more than 20.0 seconds.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the difference between the actual O2 Sensor Heater element resistance/temperature and the target resistance/temperature is not within a calibrated threshold with the O2 Sensor heater duty cycle above 89.8% for 90.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 1/2 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 1/2 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
OXYGEN (O2) SENSOR 1/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
   1. Turn the ignition off.

      NOTE: **Wait a minimum of eight minutes to allow the sensor to cool down before continuing. The sensor voltage should stabilize between 2.47 and 2.52 volts.**

   2. Turn the ignition on.
   3. With a scan tool, actuate the Oxygen Sensor 1/2 heater control.
   4. With the scan tool, monitor the O2 Sensor 1/2 voltage for at least two minutes.

   Does the voltage stay above approximately 4.5 volts?

   Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK FOR OTHER DTCS**
    1. With the scan tool, read and record DTCs on the repair order.

    Are there any other O2 Sensor Heater circuit DTCs active or pending?

    Yes

    - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

    No

    - Go To 3

3. **CHECK THE O2 SENSOR 1/2 HEATER ELEMENT RESISTANCE**
    1. Turn the ignition off.

    NOTE: **Allow the O2 Sensor heater a few minutes to cool down from the heater test performed with the scan tool.**

    2. Disconnect the O2 Sensor 1/2 harness connector.
    3. Measure the resistance of the O2 Sensor 1/2 Heater Element across the O2 Sensor, between the O2 Heater Control terminal and the Heater ground terminal (component side).

    NOTE: **If possible, it's best to measure the O2 Sensor 1/1 Heater Element resistance value at approximately 20B°C (68B°F). The resistance value will vary with different temperature values. If the O2 Sensor is obviously warmer or cooler than the recommended temperature, use the table below to estimate what the resistance range should be. The MAXIMUM allowable resistance would be 12.5 Ohms at 1000B°C.**

Celsius	Fahrenheit	Resistance Range
0B°C	32B°F	3.1 - 4.2 Ohms
20B°C	68B°F	3.3 - 4.4 Ohms
100B°C	212B°F	3.85 - 5.1 Ohms

    Is the O2 Sensor resistance within the acceptable range?

    Yes

    - Go To 4

    No

    - Verify that there is good pin to terminal contact in the Sensor and Control Module connectors. If no problems are found, replace the O2 Sensor. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND LOAD TEST THE O2 SENSOR 1/2 (K299) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**

1. The ignition must be off when performing a load test on a circuit.
2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

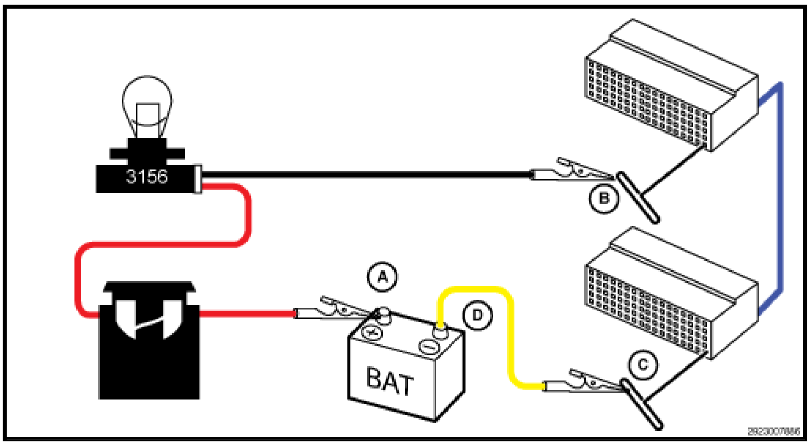
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
- **3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: **To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.**

CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 5

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **ISOLATE AND LOAD TEST THE (Z910) GROUND CIRCUIT TO CHECK FOR HIGH RESISTANCE**
   1. The ignition must be off when performing a load test on a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.

3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

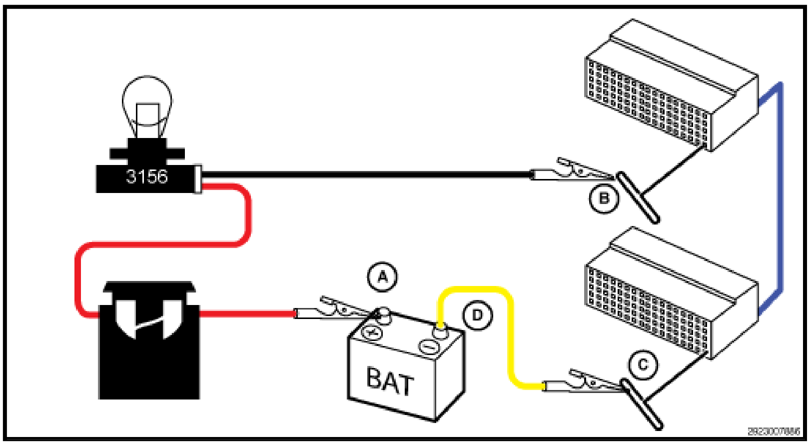
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
- **3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: **To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.**

CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 6

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK RELATED HARNESS CONNECTIONS**
   1. Disconnect all PCM harness connectors.
   2. Disconnect all related in-line harness connections (if equipped).
   3. Disconnect the related component harness connectors.
   4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.

- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0151-O2 SENSOR 2/1 CIRCUIT LOW

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms

	resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.**
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts**

Using the Scan Tool for Diagnostics:	
	and increase toward 0.0 volts as the sensor heats up. When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Battery voltage between 11.0 and 15.75 volts.
- With the engine running.

SET CONDITION

- The Oxygen Sensor 2/1 signal voltage is less than 0.0 volts for 9.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/1 SIGNAL CIRCUIT SHORTED TO GROUND
O2 SENSOR 2/1 SIGNAL CIRCUIT SHORTED TO THE O2 SENSOR 2/1 HEATER GROUND CIRCUIT
O2 SENSOR 2/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.

3. Connect the negative lead of the DVOM to a known good ground.
4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, (special tool #10436, Adapter, GPEC Diagnostic) connect the to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 4

4. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR A SHORT TO THE (Z910) GROUND CIRCUIT**
   1. The ignition must be off when checking for a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between the circuits being tested.**

   Is there continuity between the circuits?

   Yes

   - Repair the short between the circuits.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

- Go To 5

5. **CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

    Is the O2 Sensor 2/1 voltage above 4.0 volts?

    Yes

    - Replace the O2 Sensor 2/1 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 6

6. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.

10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0152-O2 SENSOR 2/1 CIRCUIT HIGH

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.

- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between**

	approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.

Using the Scan Tool for Diagnostics:	
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage is between 11.0 volts and 15.8 volts.

SET CONDITION

- The PCM detects that Oxygen Sensor 2/1 signal voltage is greater than 1.20 volts.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/1 HEATER CONTROL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 2/1 HEATER CONTROL CIRCUIT SHORTED TO GROUND
O2 SENSOR 2/1 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/1 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/1 SIGNAL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 2/1 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/1 RETURN CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
    1. Start the engine and allow it to idle for at least 60 seconds.

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

2. With the scan tool, read the O2 Sensor 2/1 signal voltage.

   Is the voltage staying above 4.0 volts?

   Yes

   - Go To 2

   No

   - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK THE O2 SENSOR 2/1 HEATER OPERATION**
   1. With the scan tool, check the O2 Sensor 2/1 duty cycle. Also monitor the O2 Sensor 2/1 heater temperature and compare to the other O2 Sensor heater temperatures.

   NOTE: **The duty cycle percentage and heater temperature should be relatively close to the other sensors. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably different than the other O2 Sensors.**

   Is the O2 Sensor heater operating properly?

   Yes

   - Go To 7

   No

   - Go To 3

3. **CHECK THE O2 SENSOR 2/1 (Z910) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
   1. Disconnect the component harness connector to isolate the ground circuit.
   2. Connect the positive lead of the load test tool to the positive side of the Battery.
   3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
   4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

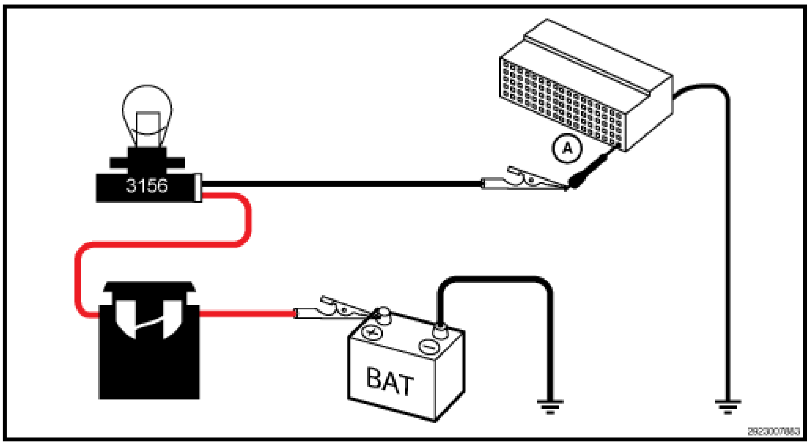
NOTE: **Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.

   NOTE: Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.

   Is the load test bulb illuminated and bright?

Yes

- Go To 4

No

- Repair the ground circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K199) HEATER CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
   4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

   Is there continuity between the circuit being tested and any other circuit?

   Yes

   - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5

5. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K199) HEATER CONTROL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to**

pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

No

- Go To 6

6. **ISOLATE AND LOAD TEST THE O2 SENSOR 2/1 (K199) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
   1. The ignition must be off when performing a load test on a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
   3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
   4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at one of the component harness connectors (B).
   5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
   6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

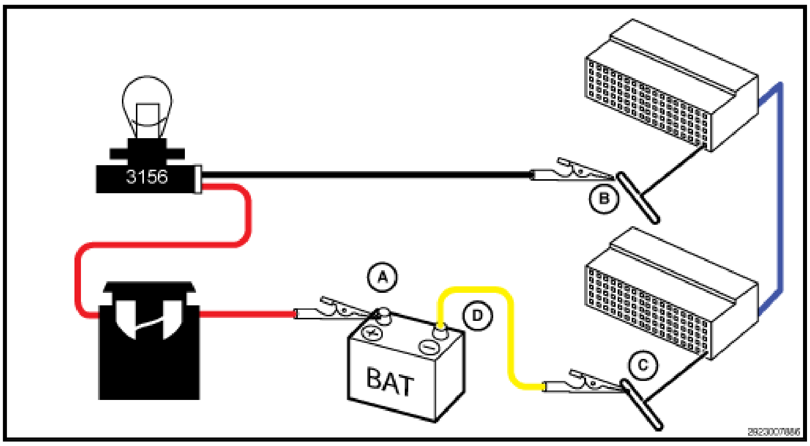
NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage**

drop test across the 3156 bulb of the load test tool. To do so perform the following:

1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: Do not load test any circuits with components still connected to the circuit.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.

Is the load test bulb illuminated and bright?

Yes

- Go To 10

No

- Repair the circuit for an open or high resistance.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

    NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

    Is the voltage above 5.2 volts?

    Yes

    - Repair the (K43) O2 Sensor 2/1 Signal circuit for a short to voltage.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 8

8. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

        NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

        Is the resistance below 3.0 Ohms?

        Yes

        - Go To 9

        No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

9. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K902) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 10

    No

    - Repair the circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **REPLACE THE O2 SENSOR 2/1 AND RETEST FOR DTC**
    1. Replace the O2 Sensor 2/1 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    2. Connect the O2 Sensor 2/1 and PCM harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs.
    5. Using the recorded Freeze Frame and the When Monitored conditions, operate the vehicle in the conditions that set the DTC.
    6. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 11

    No

    - Replacing the O2 Sensor repaired the fault.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0153-O2 SENSOR 2/1 SLOW RESPONSE

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Upstream Oxygen (O2) Sensor is usually placed close to the exhaust manifold to achieve fast light-off and provide immediate O2 feedback to allow the fuel system to enter closed loop fuel control.

The Upstream O2 Sensor is very important for emission control and engine performance since it can provide immediate air/fuel ratio feedback. Therefore, proper operation of this Upstream O2 Sensor is critical. An aged Upstream O2 Sensor tends to be less active and has a slower response rate to changes in the air/fuel ratio of exhaust gas. As a result, the quality of the Upstream O2 Sensor can be determined by observing the voltage activity from the sensor.

This monitor is triggered when the engine is running at certain MAP/RPM windows, airflow is relatively stable and steady O2 control is applied. The state change for Upstream O2 signal is captured in a calibrated time block (consisting of consecutive samples), such that even the slowest (but still considered as passing) O2 Sensor should accumulate enough state changes to pass the monitor.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Engine Coolant Temperature (ECT) Sensor value is above 70 B°C (158 B°F).
- Engine speed between 1400 and 2300 rpm.
- Vehicle speed between 64 and 96 km/h (40 and 60 mph).
- Engine run time greater than three minutes.

SET CONDITION

- PCM detects that the Oxygen Sensor signal does not switch adequately during monitoring.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
EXHAUST LEAK
O2 SENSOR 2/1 SIGNAL CIRCUIT
O2 SENSOR 2/1 RETURN CIRCUIT
OXYGEN (O2) SENSOR 2/1

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.

7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECKING THE EXHAUST SYSTEM FOR LEAKS**
    1. Perform the CHECKING THE EXHAUST SYSTEM FOR LEAKS test procedure. Refer to **CHECKING THE EXHAUST SYSTEM FOR LEAKS** .

    Were any exhaust leaks found?

    Yes

    - Repair or replace the leaking exhaust parts as necessary.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 3

3. **CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **Normal operating voltage should be between 4.1 and 5.0 volts.**

Does the circuit have the proper voltage present?

Yes

- Go To 8

No

- Go To 4

4. **CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

    NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

    Is the voltage above 5.2 volts?

    Yes

    - Go To 5

    No

    - Go To 6

5. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

        NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

        Is there continuity between the circuit being tested and any other circuit?

        Yes

        - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Go To 14

6. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.

3. Connect the negative lead of the DVOM to a known good ground.
4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 7

7. **ISOLATE AND CHECK THE O2 SENSOR 2/1 (K43) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 13

   No

   - Repair the circuit for an open or high resistance.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **CHECK THE (K902) SENSOR RETURN UPSTREAM CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

        NOTE: **Normal operating voltage should be approximately 2.5 volts.**

        Does the circuit have the proper voltage present?

        Yes

        - Go To 13

        No

        - Go To 9

9. **CHECK THE (K902) SENSOR RETURN UPSTREAM CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

    NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

    Is the voltage above 5.2 volts?

    Yes

    - Go To 10

    No

    - Go To 11

10. **ISOLATE AND CHECK THE (K902) SENSOR RETURN UPSTREAM CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**

1. The ignition must be off when performing a resistance check to find a short between circuits.
2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

Is there continuity between the circuit being tested and any other circuit?

Yes

- Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 14

11. **ISOLATE AND CHECK THE (K902) SENSOR RETURN UPSTREAM CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 12

12. **ISOLATE AND CHECK THE (K902) SENSOR RETURN UPSTREAM CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   Is the resistance below 3.0 Ohms?

   Yes

   - Repair the (K902) O2 Return Upstream circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 13

13. **CHECK THE O2 SENSOR 2/1 WIRING AND CONNECTOR**

NOTE: **Check for signs of contaminants that may have damaged the O2 Sensor, such as contaminated fuel, unapproved silicone, oil and coolant.**

1. Using the wiring diagram/schematic as a guide, inspect the wiring and connectors between the O2 Sensor 2/1 and the Powertrain Control Module (PCM).
   - Look for any chafed, pierced, pinched, or partially broken wires.
   - Look for broken, bent, pushed out or corroded terminals.
   - Verify that there is good pin to terminal contact in the O2 Sensor 2/1 and Powertrain Control Module connectors.
   - Perform any Service Bulletins that may apply.

   Were any problems found?

   Yes

   - Repair as necessary.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Replace the O2 Sensor 2/1 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace the Powertrain Control Module (PCM) in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

- Test complete.

P0155-O2 SENSOR 2/1 HEATER PERFORMANCE

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.

- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver**

	and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Engine coolant temperature at start up and Ambient temperature are greater than 7B°C (45B°F).
- The difference between coolant temperature at engine start and ambient temperature is greater than 9B°C (48B°F).
- The O2 Heater temperature is greater than 401B°C (754B°F).
- Battery voltage is between 11.0 volts and 15.8 volts.

SET CONDITION

- No temperature change is detected in the O2 Sensor 2/1 Heater element when the heater circuit is active.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/1 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/1 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
OXYGEN (O2) SENSOR 2/1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
    1. Turn the ignition off.

       NOTE: **Wait a minimum of eight minutes to allow the sensor to cool down before continuing. The sensor voltage should stabilize between 2.47 and 2.52 volts.**

    2. Turn the ignition on.
    3. With a scan tool, actuate the Oxygen Sensor 2/1 heater control.
    4. With the scan tool, monitor the O2 Sensor 2/1 voltage for at least two minutes.

       Does the voltage stay above approximately 4.5 volts?

       Yes

       - Go To 2

       No

       - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECK FOR OTHER DTCS**
    1. With the scan tool, read and record DTCs on the repair order.

       Are there any other O2 Sensor Heater circuit DTCs active or pending?

Yes

- Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

No

- Go To 3

3. **CHECK THE O2 SENSOR 2/1 HEATER ELEMENT RESISTANCE**
    1. Turn the ignition off.
    2. Disconnect the O2 Sensor 2/1 harness connector.
    3. Measure the resistance of the O2 Sensor 2/1 Heater Element across the O2 Sensor, between the O2 Heater Control terminal and the Heater ground terminal (component side).

    NOTE: **If possible, it's best to measure the O2 Sensor 1/1 Heater Element resistance value at approximately 20B°C (68B°F). The resistance value will vary with different temperature values. If the O2 Sensor is obviously warmer or cooler than the recommended temperature, use the table below to estimate what the resistance range should be. The MAXIMUM allowable resistance would be 12.5 Ohms at 1000B°C.**

Celsius	Fahrenheit	Resistance Range
0B°C	32B°F	3.1 - 4.2 Ohms
20B°C	68B°F	3.3 - 4.4 Ohms
100B°C	212B°F	3.85 - 5.1 Ohms

    Is the O2 Sensor resistance within the acceptable range?

    Yes

    - Go To 4

    No

    - Verify that there is good pin to terminal contact in the Sensor and Control Module connectors. If no problems are found, replace the O2 Sensor. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
4. **ISOLATE AND LOAD TEST THE O2 SENSOR 2/1 (K199) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
    1. The ignition must be off when performing a load test on a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
    3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
    4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
    5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
    6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

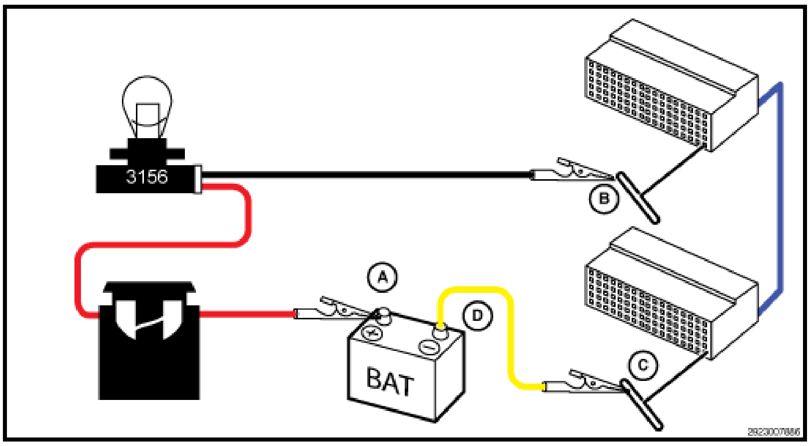
NOTE: Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .

NOTE: Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

- 1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
- 2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
- 3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.

CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 5

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **ISOLATE AND LOAD TEST THE (Z910) GROUND CIRCUIT TO CHECK FOR HIGH RESISTANCE**
   1. The ignition must be off when performing a load test on a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
   3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
   4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
   5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
   6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

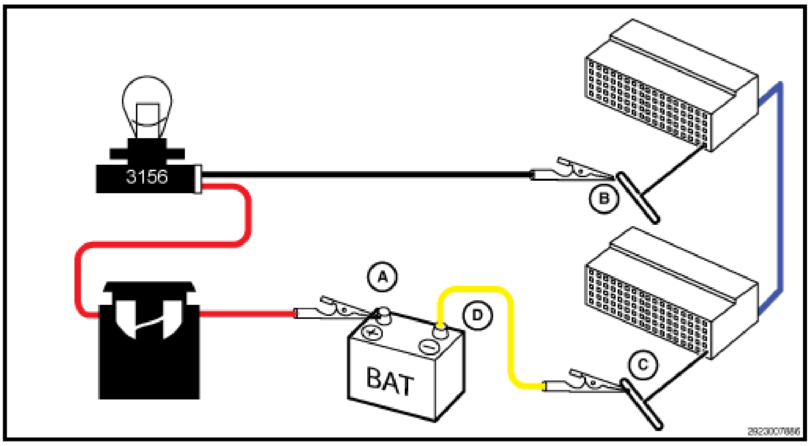
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

- 1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
- 2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
- 3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.

CAUTION: Do not load test any circuits with components still connected to the circuit.

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 6

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK RELATED HARNESS CONNECTIONS**
   1. Disconnect all PCM harness connectors.
   2. Disconnect all related in-line harness connections (if equipped).
   3. Disconnect the related component harness connectors.
   4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.

   5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. With the scan tool, erase DTCs.
   9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
   10. With the scan tool, read DTCs.

   Did the DTC return?

   Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0157-O2 SENSOR 2/2 CIRCUIT LOW

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this

case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between**

	approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will

Using the Scan Tool for Diagnostics:	
	cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Battery voltage between 11.0 and 15.75 volts.
- With the engine running.

SET CONDITION

- The Oxygen Sensor 2/2 signal voltage is less than 0.0 volts for 9.0 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/2 SIGNAL CIRCUIT SHORTED TO GROUND
O2 SENSOR 2/2 SIGNAL CIRCUIT SHORTED TO THE O2 SENSOR 2/2 HEATER GROUND CIRCUIT
O2 SENSOR 2/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
3. **ISOLATE AND CHECK THE O2 SENSOR (K243) 2/2 SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, (special tool #10436, Adapter, GPEC Diagnostic) connect the to the appropriate PCM harness connector.

        NOTE: **There should be no continuity between ground and the circuit being tested.**

        Is there continuity between ground and the circuit being tested?

        Yes

        - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

- Go To 4

4. **ISOLATE AND CHECK THE O2 SENSOR (K243) 2/2 SIGNAL CIRCUIT FOR A SHORT TO THE (Z910) GROUND CIRCUIT**
    1. The ignition must be off when checking for a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    NOTE: **There should be no continuity between the circuits being tested.**

    Is there continuity between the circuits?

    Yes

    - Repair the short between the circuits.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 5

5. **CHECK THE O2 SENSOR (K243) 2/2 SIGNAL CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

Is the O2 Sensor 2/2 voltage above 4.0 volts?

Yes

- Replace the O2 Sensor 2/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - The wiring or poor connection problem has been repaired.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0158-O2 SENSOR 2/2 CIRCUIT HIGH

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and

heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool.

NOTE:

When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even

Using the Scan Tool for Diagnostics:	
	a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.

- Battery voltage between 11.0 volts and 15.8 volts.

SET CONDITION

- The PCM detects that Oxygen Sensor 2/2 signal voltage is greater than 1.20 volts.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/2 HEATER CONTROL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 2/2 HEATER CONTROL CIRCUIT SHORTED TO GROUND
O2 SENSOR 2/2 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/2 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/2 SIGNAL CIRCUIT SHORTED TO VOLTAGE
O2 SENSOR 2/2 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/2 RETURN CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
    1. Start the engine and allow it to idle for at least 60 seconds.

       WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    2. With the scan tool, read the O2 Sensor 2/2 signal voltage.

       Is the voltage staying above 4.0 volts?

       Yes

       - Go To 2

       No

       - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECK THE O2 SENSOR 2/2 HEATER OPERATION**
    1. With the scan tool, check the O2 Sensor 2/2 duty cycle. Also monitor the O2 Sensor 2/2 heater temperature and compare to the other O2 Sensor heater temperatures.

       NOTE: **The duty cycle percentage and heater temperature should be relatively close to the other sensors. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry,**

even a small amount of resistance, will cause the temperature reading to be noticeably different than the other O2 Sensors.

Is the O2 Sensor heater operating properly?

Yes

- Go To 7

No

- Go To 3

3. **CHECK THE O2 SENSOR 2/2 (Z910) GROUND CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
    1. Disconnect the component harness connector to isolate the ground circuit.
    2. Connect the positive lead of the load test tool to the positive side of the Battery.
    3. Connect the negative lead of the load test tool to the ground circuit at the component harness connector (A). **Note:** refer to the diagram below.
    4. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

NOTE: **Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

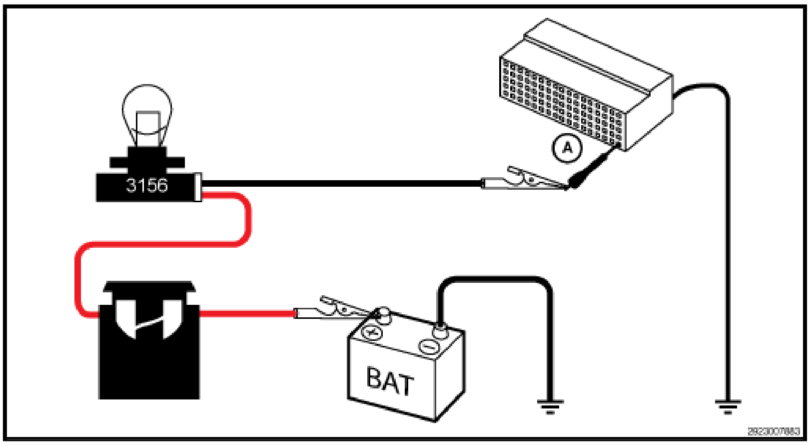
NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and

alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 4

   No

   - Repair the ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K399) HEATER CONTROL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
   4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

   Is there continuity between the circuit being tested and any other circuit?

   Yes

   - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5

5. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K399) HEATER CONTROL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

   CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 6

6. **ISOLATE AND LOAD TEST THE O2 SENSOR 2/2 (K399) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
   1. The ignition must be off when performing a load test on a circuit.

2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at one of the component harness connectors (B).
5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

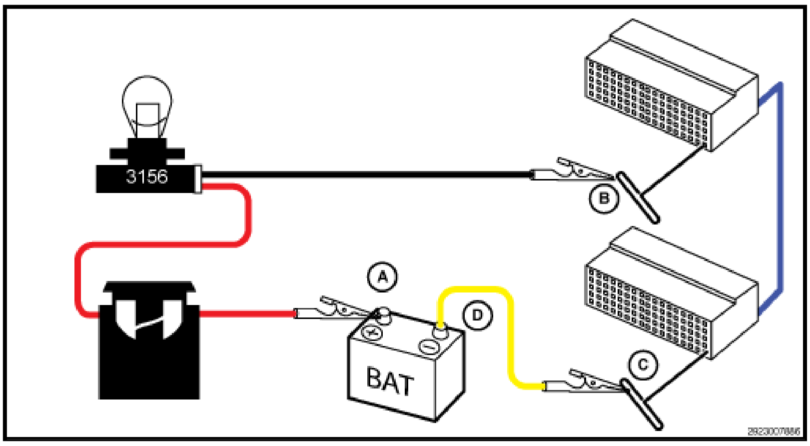
NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 10

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **CHECK THE O2 SENSOR 2/2 (K243) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
   1. Turn the ignition off.
   2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Turn the ignition on.
   4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

Is the voltage above 5.2 volts?

Yes

- Repair the O2 Sensor 2/2 (K141) Signal circuit for a short to voltage.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 8

8. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K243) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 9

    No

    - Repair the circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

9. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K904) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 10

    No

    - Repair the circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **REPLACE THE O2 SENSOR 2/2 AND RETEST FOR DTC**
    1. Replace the O2 Sensor 2/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    2. Connect the O2 Sensor 2/2 and PCM harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs.
    5. Using the recorded Freeze Frame and the When Monitored conditions, operate the vehicle in the conditions that set the DTC.
    6. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 11

    No

    - Replacing the O2 Sensor repaired the fault.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

11. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0159-O2 SENSOR 2/2 SLOW RESPONSE

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

For an aged Oxygen (O2) Sensor, the response rate to the air/fuel change is slower than when it was new. The O2 Sensor tends to move less with the same air/fuel changes in a given time frame. Therefore by observing the activity of voltage readings from the O2 Sensor, the quality of the O2 Sensor can be detected.

The Downstream O2 Sensor is located in the exhaust path behind the Catalytic Converter, and is monitored for proper response to assure optimum Catalytic Converter efficiency. This occurs by monitoring the change in the Downstream O2 Sensor voltage over time, when the fuel is shut off during a decel condition after the enable conditions were met. If the slope of the Downstream O2 Sensor is too small, the monitor will fail indicating that the O2 Sensor is not reliable enough to monitor Catalytic Converter efficiency.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- With the engine running.
- Vehicle speed above 96 km/h (60 mph).
- Engine Coolant Temperature (ECT) Sensor value greater than 70B°C (158B°F).
- Throttle open for a minimum of 120 seconds.
- Catalytic Converter temperature greater than 600B°C (1112B°F).
- Downstream O2 Sensor in a rich state.

- During a Decel Fuel Shutoff Event, the Downstream Oxygen Sensor should switch from rich to lean within a specific time.

SET CONDITION

- If the PCM does not detect a rich to lean switch within a specific time during a decel fuel shutoff event, the monitor will fail.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
EXHAUST LEAK
O2 SENSOR 2/2 SIGNAL CIRCUIT
O2 SENSOR 2/2 RETURN CIRCUIT
OXYGEN (O2) SENSOR 2/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
   1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
   2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
   3. With the scan tool, erase all DTCs.
   4. Turn the ignition off for a minimum of 10.0 seconds.
   5. Turn the ignition on.
   6. Using the When Monitored Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
   7. With the scan tool, read DTCs.

   Did the DTC return?

   Yes

   - Go To 2

   No

   - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECKING THE EXHAUST SYSTEM FOR LEAKS**
   1. Perform the CHECKING THE EXHAUST SYSTEM FOR LEAKS test procedure. Refer to **CHECKING THE EXHAUST SYSTEM FOR LEAKS** .

      Were any exhaust leaks found?

      Yes

- Repair or replace the leaking exhaust parts as necessary.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 3

3. **CHECK THE O2 SENSOR 2/2 (K243) SIGNAL CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
   1. Turn the ignition off.
   2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
   3. Turn the ignition on.
   4. Set the DVOM to measure DC voltage.
   5. Connect the negative lead of the DVOM to a known good ground.
   6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **Normal operating voltage should be between 4.1 and 5.0 volts.**

   Does the circuit have the proper voltage present?

   Yes

   - Go To 8

   No

   - Go To 4

4. **CHECK THE O2 SENSOR 2/2 (K243) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
   1. Turn the ignition off.
   2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Turn the ignition on.
   4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

Is the voltage above 5.2 volts?

Yes

- Go To 5

No

- Go To 6

5. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K243) SIGNAL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

    Is there continuity between the circuit being tested and any other circuit?

    Yes

    - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 14
6. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K243) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 7

7. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K243) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 13

    No

    - Repair the circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **CHECK THE (K904) SENSOR RETURN DOWNSTREAM CIRCUIT FOR PROPER VOLTAGE AT THE O2 SENSOR HARNESS CONNECTOR**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** The ECU harness connector should still be connected during this test step.
    3. Turn the ignition on.
    4. Set the DVOM to measure DC voltage.
    5. Connect the negative lead of the DVOM to a known good ground.
    6. With the positive lead of the DVOM, measure the voltage of the circuit being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to**

pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: **Normal operating voltage should be approximately 2.5 volts.**

Does the circuit have the proper voltage present?

Yes

- Go To 13

No

- Go To 9

9. **CHECK THE (K904) SENSOR RETURN DOWNSTREAM CIRCUIT FOR A SHORT TO VOLTAGE**
   1. Turn the ignition off.
   2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Turn the ignition on.
   4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

   Is the voltage above 5.2 volts?

   Yes

   - Go To 10

   No

   - Go To 11
10. **ISOLATE AND CHECK THE (K904) SENSOR RETURN DOWNSTREAM CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

    NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

    Is there continuity between the circuit being tested and any other circuit?

    Yes

    - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 14

11. **ISOLATE AND CHECK THE (K904) SENSOR RETURN DOWNSTREAM CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 12

12. **ISOLATE AND CHECK THE (K904) SENSOR RETURN DOWNSTREAM CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   Is the resistance below 3.0 Ohms?

   Yes

   - Repair the (K904) O2 Sensor Downstream Return circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 13

13. **CHECK THE O2 SENSOR 2/2 WIRING AND CONNECTOR**

   NOTE: **Check for signs of contaminants that may have damaged the O2 Sensor, such as contaminated fuel, unapproved silicone, oil and coolant.**

   1. Using the wiring diagram/schematic as a guide, inspect the wiring and connectors between the O2 Sensor 1/1 and the Powertrain Control Module (PCM).
      - Look for any chafed, pierced, pinched, or partially broken wires.
      - Look for broken, bent, pushed out or corroded terminals.
      - Verify that there is good pin to terminal contact in the 2/2 O2 Sensor and Powertrain Control Module connectors.
      - Perform any Service Bulletins that may apply.

      Were any problems found?

      Yes

      - Repair as necessary.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Replace the O2 Sensor 2/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).

- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace the Powertrain Control Module (PCM) in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
- Test complete.

P0160-O2 SENSOR 2/2 NO ACTIVITY DETECTED

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Downstream Oxygen (O2) Sensor no activity diagnostic monitor is intended to diagnose a Downstream O2 Sensor that is not moving or is stuck in a voltage window. This diagnostic is intended to verify the Downstream O2 Sensors ability to respond to fuel adaption deviations during the Catalyst Monitor test. To pass this monitor, the sensor must output a voltage greater than a high calibrated voltage and less than a low calibrated voltage within a calibrated time period. The test includes a non-intrusive monitor and an intrusive fueling monitor. The intrusive monitor will only run if the non-intrusive test does not pass within the calibrated time period.

The intrusive fueling routine is used to 'jolt' the fuel feedback system to force the monitor to pass. A test failure occurs if the voltage pass values are not achieved after the total accumulated test time.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Vehicle speed between 32 and 88.5 km/h (20 and 55 mph).
- Throttle open for a minimum of 120 seconds.

- Coolant temperature greater than 70B°C (158B°F).
- Catalytic Converter Temperature greater than 600B° C (1112B°F).
- EVAP Purge is active.

SET CONDITION

- The Oxygen Sensor signal voltage switches less than 16 times from lean to rich within 20 seconds during monitoring.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
EXHAUST LEAK
O2 SENSOR 2/2 SIGNAL CIRCUIT
O2 SENSOR 2/2 RETURN CIRCUIT
OXYGEN (O2) SENSOR 2/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECKING THE EXHAUST SYSTEM FOR LEAKS**
    1. Perform the CHECKING THE EXHAUST SYSTEM FOR LEAKS test procedure. Refer to **CHECKING THE EXHAUST SYSTEM FOR LEAKS** .

        Were any exhaust leaks found?

Yes

- Perform the appropriate repairs.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 3

3. **CHECK THE O2 SENSOR 2/2 (K243) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

    NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

    Is the voltage above 5.2 volts?

    Yes

    - Go To 4

    No

    - Go To 5

4. **ISOLATE AND CHECK THE O2 SENSOR 2/2 (K243) SIGNAL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

    Is there continuity between the circuit being tested and any other circuit?

    Yes

    - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

- Go To 8

5. **CHECK THE (K904) SENSOR RETURN CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

    NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

    Is the voltage above 5.2 volts?

    Yes

    - Go To 6

    No

    - Go To 7
6. **ISOLATE AND CHECK THE (K904) SENSOR RETURN CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
    1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

        NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

        Is there continuity between the circuit being tested and any other circuit?

        Yes

        - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

        No

        - Go To 8
7. **CHECK THE OXYGEN SENSOR FOR PROPER OPERATION**

    NOTE: **Check for signs of contaminants that may have damaged the O2 Sensor, such as contaminated fuel, unapproved silicone, oil and coolant.**

1. Using the wiring diagram/schematic as a guide, inspect the wiring and connectors between the Oxygen Sensor 2/2 and the Powertrain Control Module (PCM).
2. Look for any chafed, pierced, pinched or partially broken wires.
3. Look for broken, bent, pushed out or corroded terminals.
4. Perform any Service Bulletins that may apply.

   Were any problems found?

   Yes

   - Repair as necessary.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Replace the Oxygen Sensor 2/2 in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **CHECK RELATED HARNESS CONNECTIONS**
   1. Disconnect all PCM harness connectors.
   2. Disconnect all related in-line harness connections (if equipped).
   3. Disconnect the related component harness connectors.
   4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.

   5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. With the scan tool, erase DTCs.
   9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
   10. With the scan tool, read DTCs.

      Did the DTC return?

      Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0161-O2 SENSOR 2/2 HEATER PERFORMANCE

For a complete CATALYST MONITOR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

O2 Sensor Heater Operation: For a typical Switching (4 Wire) Oxygen (O2) Sensor output signal to function the sense element must be heated to operating temperature. A resistive heater element is incorporated within the sensor to allow for rapid heating of the sensor to reach operating temperature faster and closed loop fuel control. The O2 Sensor Heater resistance is directly proportional to the heater temperature, meaning that as heater temperature increases, the heater resistance increases. The Powertrain Control Module (PCM) makes a calculation to determine the heater resistance and temperature. The heater resistance is calculated by measuring the Battery voltage and current draw on the heater control circuit, Then the heater temperature is determined using the resistance versus temperature characteristic. The heater temperature is monitored continuously and the heating rate is adjusted using Pulse Width Modulation (PWM) to prevent damaging the heating element. If the PCM detects a fault in the O2 Sensor heater circuitry the internal PCM driver is disabled during the current ignition cycle.

O2 Sensor Output Operation: Normal range of the O2 Sensor output is a 0 to 1.0 volt Analog to Digital (A/D) signal when the sensor is within the normal operating temperature range. The output voltage is generated by comparing the Oxygen content in the atmosphere, collected in a reference chamber to the Oxygen content in the exhaust stream collected in a comparison chamber. When the oxygen content is high (caused by a lean air/fuel mixture) the sensor produces a low voltage. When the oxygen content is low (caused by a rich air/fuel mixture) it produces a higher voltage. In some instances a negative offset output of up to -1.0 volt may be introduced if the sensor's reference chamber is contaminated. To allow for the negative voltage to be read, each O2 Sensor Return circuit has a 2.5 volt bias added to shift the signal voltage to between 2.5 volts and 3.5 volts.

O2 Sensor Diagnostics: The Powertrain Control Module (PCM) performs diagnostics on the heater control, signal and sensor return circuits. The circuit fault diagnostics for O2 Sensors are algorithm based because of how the O2 Sensor operates. This means an open or short in one of the O2 Sensor circuits can cause a fault to set against another of the O2 Sensor circuits. Understanding how to interpret the combination of DTCs and O2 Sensor data provided can aid in narrowing down where the fault is in the system.

- **On vehicle/engine combinations that use only the traditional switching O2 Sensors,** both of the Upstream and Downstream O2 Sensor Return circuits originate from a single source within the PCM. Because of this, a short anywhere in the wiring in any of the O2 Sensor Return circuits will affect all of the Upstream and Downstream O2 Sensors.
- **On vehicle/engine combinations that have wide-band Upstream O2 Sensors and switching Downstream O2 Sensors,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this case a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s). The PCM performs individual diagnostics on the O2 Sensor Return circuit for each wide-band Upstream O2 Sensor.
- **On vehicle/engine combinations that use only the traditional switching O2 Sensors with GPEC 5 PCM,** the Upstream and Downstream O2 Sensor Return circuits are separate within the PCM. In this

case a short anywhere in the wiring in the Upstream O2 Sensor Return circuit(s) will only affect the Upstream O2 Sensor(s) and a short anywhere in the wiring in the Downstream O2 Sensor Return circuit(s) will only affect the Downstream O2 Sensor(s).

With the scan tool in data display, filter on O2 in the search function and bring up the following info:

- **O2 Sensor signal voltage** - the **biased signal voltage** should switch between 2.5 and 3.5 volts on a normally functioning sensor.
- **O2 Sensor (0-1) signal voltage** - this is the **raw O2 Sensor signal voltage** without the 2.5 volt bias on the return circuit of a normally functioning O2 Sensor.
- **Heater driver operation** - displays the heater duty cycle.
- **Heater temperature** - this is determined by the total heater circuit resistance.
- **Closed loop fuel control state** - displays as open/closed.

Using the Scan Tool for Diagnostics:	
O2 Sensor Heater Diagnosis:	An open circuit or direct short to voltage or ground will cause the PCM to disable the heater PWM control. The heater will remain disabled for the remainder of that ignition cycle, even if the condition is intermittent and heals itself during that ignition cycle. Any of these conditions should set an O2 Sensor Heater Low or High DTC. **Since the heater directly affects the output of sensor signal,** and the heater control is disabled, this will cause the affected O2 Sensor biased signal voltage to read high (usually stays above 4.0 volts) and can also eventually set a **Signal Circuit High DTC** . It is not unusual to have both a Heater Control Circuit High or Low DTC and a Sensor Signal High DTC for the same sensor. **Important Note: A small amount of resistance (3-4 Ohms) may not set a Heater Control Circuit DTC but will affect heater operation and cause the Sensor Signal High DTC to set.** Monitoring the heater duty cycle and temperature for a sensor that is reading high on the biased signal voltage can help in diagnosing this issue. A heater circuit with 4.0 - 5.0 Ohms resistance can increase the heater temperature reading on the scan tool for the affected sensor by as much as 700B°F when compared to the other Switching (4 wire) O2 Sensors. As little as 2.0 Ohms can increase the temperature reading approximately 250B°F on the scan tool. **NOTE:** **When a normally operating Switching O2 Sensor is heated to operating temperature the typical duty cycle percentage will range between approximately 30 and 50 percent. The typical heater temperature will range between**

	approximately 1200B°F and 1400B°F on the scan tool. If there is an issue with the O2 Sensor heater or circuitry the PCM will disable the heater driver and the duty cycle will be 0 percent. Any issues in the heater circuitry, even a small amount of resistance, will cause the temperature reading to be noticeably higher than normal.
O2 Sensor Signal Low Diagnosis:	Monitoring the scan tool and starting the engine with an **O2 Sensor Signal shorted to ground** , and the O2 Sensor is cold, will show the biased signal voltage at 0 volts **but the (0-1) raw voltage signal will read -2.5 volts and increase toward 0.0 volts as the sensor heats up.** When the sensor is warm the biased signal voltage reading and the (0-1) raw voltage reading will both read near 0.0 volts. It will also pull the sensor return bias voltage low through the O2 Sensor. This will cause the **biased voltage signals** to read between the 0-1 volt range on the other O2 Sensors. **This can also cause the O2 Sensor Reference (Return) Voltage Circuit Low DTC to set.**
O2 Sensor Signal High Diagnosis:	The O2 Sensor Signal High diagnostic can fail due to several conditions. A open, short or any resistance in the **heater circuitry** can cause the signal voltage to remain high. Look for abnormalities in the heater duty cycle or heater temperature of the affected sensor to help indicate a possible heater control issue causing the signal circuit high fault. An open in a sensor return circuit will cause the biased signal voltage to read high, near 5.0 volts, and the (0-1) raw voltage reading to be near 2.5 volts for the affected sensor or sensors. An open in the signal circuit will have the same effect on the sensor. If the Upstream or Downstream O2 Sensors are both affected, it could indicate an open in the return circuit that is before the splice in the harness.
P1621, P3090, and P3092 O2 Sensor Reference (Return) Circuit Low Diagnosis:	The O2 Sensor Reference Circuit Low/High diagnostic is used to monitor the O2 Sensor Return circuits. If any of the shared return circuits are shorted to ground the biased signal voltage readings for all O2 Sensors will switch between 0-1 volt instead of 2.5-3.5 volts. This happens because the bias voltage on the return circuit is pulled low for all shared sensors. As mentioned in the **O2 Sensor Signal Low Diagnosis** above, a short to ground in one of the sensor signal circuits will also pull the sensor return low for all shared sensors after the sensor warms up. However, this will

Using the Scan Tool for Diagnostics:	
	cause the voltage reading on the sensor that has the shorted signal to read 0.0 volts on both the biased signal voltage and (0-1) raw voltage reading when the sensor is warm.
P1622, P3091, and P3093 O2 Sensor Reference (Return) Circuit High Diagnosis:	A short to voltage in any of the shared **sensor return circuits** will cause the fault to set. The affected O2 Sensors will read 5.0 volts on the biased signal voltage. The (0-1) raw voltage reading will be 0.0 volts because the signal circuit voltage and return circuit voltage are both 5.0 volts. A short to voltage on one of the **O2 Sensor signal circuits** will cause the same fault condition and scan tool readings when the sensor is warm. If the condition is present when the engine is started and the sensor is cold, the (0-1) raw voltage reading will start at 2.5 volts and decrease to 0.0 volts as the sensor warms up.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Battery voltage between 11.0 volts and 15.8 volts.
- Engine coolant temperature at start up and Ambient temperature are greater than 7B°C (45B°F).
- The difference between coolant temperature at engine start and ambient temperature are greater than 9B°C (48B°F).
- The O2 Sensor heater temperature is greater than 401B°C (754B°F).

SET CONDITION

- No temperature change is detected in the O2 Sensor 2/2 Heater element when the heater circuit is active

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
O2 SENSOR 2/2 HEATER CONTROL CIRCUIT OPEN/HIGH RESISTANCE
O2 SENSOR 2/2 HEATER GROUND CIRCUIT OPEN/HIGH RESISTANCE
OXYGEN (O2) SENSOR 2/2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
   1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

      Are there any applicable Service Bulletins or Flash updates?

      Yes

      - Perform the applicable repair.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

      No

- Go To 2

2. **CHECK FOR AN ACTIVE CONDITION**
    1. Turn the ignition off.

    NOTE: **Wait a minimum of eight minutes to allow the sensor to cool down before continuing. The sensor voltage should stabilize between 2.47 and 2.52 volts.**

    2. Turn the ignition on.
    3. With a scan tool, actuate the Oxygen Sensor 2/2 heater control.
    4. With the scan tool, monitor the O2 Sensor 2/2 voltage for at least two minutes.

    Does the voltage stay above approximately 4.5 volts?

    Yes

    - Go To 3

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

3. **CHECK FOR OTHER DTCS**
    1. With the scan tool, read and record DTCs on the repair order.

    Are there any other O2 Sensor Heater circuit DTCs active or pending?

    Yes

    - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

    No

    - Go To 4

4. **CHECK THE O2 SENSOR 2/2 HEATER ELEMENT RESISTANCE VALUE**
    1. Turn the ignition off.

    NOTE: **Allow the O2 Sensor heater a few minutes to cool down from the heater test performed with the scan tool.**

    2. Disconnect the O2 Sensor 2/2 harness connector.
    3. Measure the resistance of the O2 Sensor Heater Element inside the O2 Sensor. Measure between the O2 Heater Control circuit terminal and the O2 Heater ground circuit terminal.

    NOTE: **If possible, it's best to measure the O2 Sensor 1/1 Heater Element resistance value at approximately 20B°C (68B°F). The resistance value will vary with different temperature values. If the O2 Sensor is obviously warmer or cooler than the recommended temperature, use the table below to estimate what the resistance range should be. The MAXIMUM allowable resistance would be 12.5 Ohms at 1000B°C.**

Celsius	Fahrenheit	Resistance Range
0B°C	32B°F	3.1 - 4.2 Ohms
20B°C	68B°F	3.3 - 4.4 Ohms

Celsius	Fahrenheit	Resistance Range
100B°C	212B°F	3.85 - 5.1 Ohms

Is the O2 Sensor resistance within the acceptable range?

Yes

- Go To 5

No

- Verify that there is good pin to terminal contact in the O2 Sensor 2/2 and Powertrain Control Module connectors. If OK, replace the O2 Sensor 2/2. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **ISOLATE AND LOAD TEST THE O2 SENSOR 2/2 (K399) HEATER CONTROL CIRCUIT TO CHECK FOR HIGH RESISTANCE**
    1. The ignition must be off when performing a load test on a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
    3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
    4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
    5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
    6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

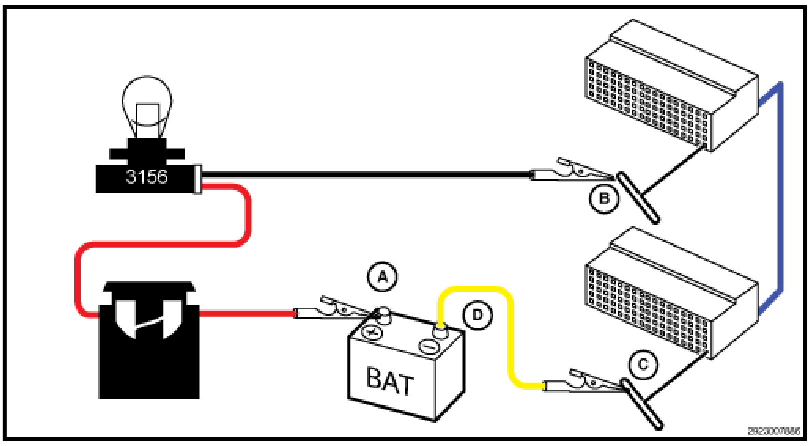
NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**

- 2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
- 3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: **To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.**

CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

- Go To 6

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **ISOLATE AND LOAD TEST THE (Z910) GROUND CIRCUIT TO CHECK FOR HIGH RESISTANCE**
    1. The ignition must be off when performing a load test on a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested.
    3. Connect the positive lead of the load test tool to the positive side of the Battery (A). **Note:** Refer to the diagram below.
    4. Using an approved back probe tool, connect the negative lead of the load test tool to the circuit being tested at the one of the component harness connectors (B).
    5. Using an approved back probe tool and a fused jumper wire, connect the circuit being tested to the negative side of the Battery or a known good ground at the other component harness connector (C and D).
    6. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuit.

NOTE: **Note: Why load test a circuit? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

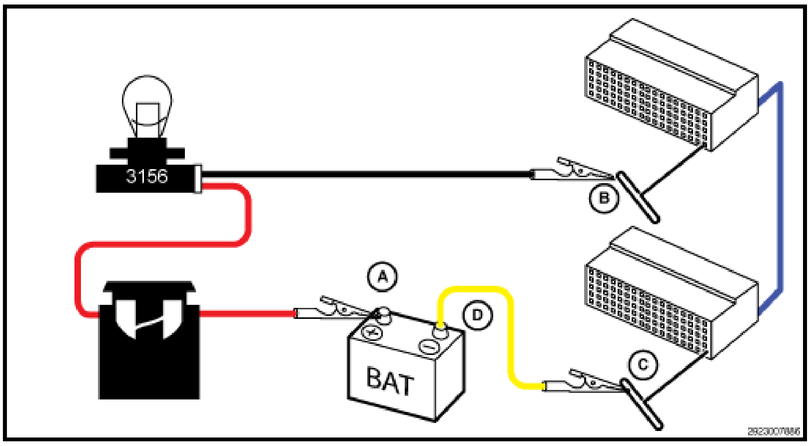
NOTE: **Note: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Note: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

- **1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
- **2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
- **3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit

makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



WARNING: **To avoid possible serious or fatal injury, DO NOT load test any air bag/restraint system components or circuits using the procedures listed here. Refer to the Service Information for proper air bag/restraint system testing procedures.**

CAUTION: **Do not load test any circuits with components still connected to the circuit.**

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 7

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

7. **CHECK RELATED HARNESS CONNECTIONS**
   1. Disconnect all PCM harness connectors.
   2. Disconnect all related in-line harness connections (if equipped).
   3. Disconnect the related component harness connectors.

4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
    - Proper connector installation.
    - Damaged connector locks.
    - Corrosion.
    - Other signs of water intrusion.
    - Weather seal damage (if equipped).
    - Bent terminals.
    - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
    - Terminals that have been pushed back into the connector cavity.
    - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

DIAGNOSIS AND TESTING

P0304-CYLINDER 4 MISFIRE

THEORY OF OPERATION

The PCM uses the Crankshaft Position (CKP) Sensor to detect and monitor the Crankshaft rotational speed. Normally, the Crankshaft rotational speed is fairly stable from cylinder to cylinder. When a misfire occurs in a cylinder, the Crankshaft speed changes abruptly for that cylinder. Therefore, anything that causes a sudden change in Crankshaft speed detected for a single cylinder is determined to be an engine misfire event. A misfire fault will usually occur due to poor fuel quality or metering, lack of spark, engine timing, low engine compression due to engine mechanical or valvetrain issues, a vacuum leak or coolant leak entering the engine intake air system. Though not as common, other factors such as severe wheel balance or braking vibration, a worn serpentine belt or belt driven accessory binding should also be considered when diagnosing a misfire fault.

Depending on the engine involved, there can be several systems and components that can contribute to a misfire. **In many cases, but not always, there will be other DTCs set related to these systems. If that is the case, the focus should be on following the diagnostics for the system that has DTCs set against it.** The different components or systems will affect misfire in different ways. Factors to consider when diagnosing a misfire are whether the misfire is a single cylinder or multiple cylinder misfire, and when does the misfire occur (idle, vehicle and engine speed, heavy engine load conditions, etc.). These factors can help in determining what components or systems should be focused on during diagnostics. **Typically a multiple cylinder misfire is an indication of timing, oil or coolant consumption, air handling, fuel supply or poor fuel quality issue that can affect multiple cylinders and not a single cylinder component such as a Fuel Injector, Ignition Coil or Spark Plug.**

NOTE: **The effects that the components and systems have on misfire detection are described in more detail in the individual test steps below.**

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Fuel level above 12%.
- Battery voltage above 10.9 volts.
- The adaptive numerator has been successfully learned.
- Ambient temperature above -23B°C (-9.4B°F).
- Coolant temperature at engine start is above -7B°C (19.4B°F). If start engine temperature is below threshold, enable monitor when engine temperature reaches 21B°C (69.8B°F).
- Engine speed between approximately 400 rpm and 6200 rpm.
    - Misfire monitor is disabled during a Decel Fuel Shutoff Event (DFSO).

SET CONDITION

- The variation in crankshaft speed between cylinders exceeds a calibrated value, based on engine speed and load.

DEFAULT ACTION

- The MIL light will illuminate or flash depending on severity of the misfire.
- During a severe misfire (MIL Light flashing) the PCM will disable the Fuel Injector of the affected cylinder(s) for a calibrated number of engine revolutions to prevent damage to the Catalytic Converter.

When the engine rev counter has reached the calculated threshold the Fuel Injector is turned back on. If a misfire is still occurring, the injector is disabled again. This cycle will continue until the misfire has stopped.

- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
ENGINE VACUUM LEAK
FAULTY FUEL INJECTOR
FAULTY IGNITION COIL OR SPARK PLUG
CRANKSHAFT POSITION SENSOR (CKP) OR TONE WHEEL ISSUES
EXCESSIVE CARBON BUILD-UP OR VALVETRAIN ISSUE
VARIABLE VALVE LIFT (VVL) SYSTEM ISSUES (IF EQUIPPED)
COOLANT LEAKING INTO A CYLINDER
ENGINE MECHANICAL SYSTEM
WORN CAMSHAFT LOBES, SPRINGS OR ROCKER ARMS
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
    1. Turn the ignition on.
    2. With the scan tool, read and record all DTCs and Freeze Frame information.
    3. Operate the vehicle under conditions recorded in the Freeze Frame information when the DTC was set.

        NOTE: **During the test drive of the vehicle, note when the misfire condition is present for use later in this diagnostic test. Also monitor the Downstream O2 Sensor(s) when the misfire is occurring. O2 Sensor voltage readings that are consistently on the low side of the scale would indicate a lean condition. This could indicate a lack of fuel due to a plugged Fuel Injector or fuel system issue. O2 Sensor voltage readings that are consistently on the high side of the scale would indicate a rich condition. This could be caused by a lack of spark or a possible leaky Fuel Injector.**

        NOTE: **Keep in mind that during a severe misfire (MIL Light flashing) the PCM will disable the Fuel Injector of the affected cylinder(s) for a calibrated number of engine revolutions to prevent damage to the Catalytic Converter. This can cause a misfire that occurs only at high engine speed or heavy engine load to appear to continue when returning to idle. However this could be due to the Fuel Injector being disabled until the rev counter resets.**

    4. With the scan tool, view the Misfire Monitor to see which cylinders are effected.

        Are there excessive misfires shown for this cylinder at this time?

        Yes

        - Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

   Are there any Service Bulletins or fuel system, ignition system component, air handling component, VVL system (if equipped), or VVT system DTCs active or pending?

   Yes

   - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

   No

   - Go To 3

3. **CHECK FOR MECHANICAL CONDITIONS THAT COULD CAUSE A MISFIRE**

   NOTE: **Each of the following conditions can cause a misfire during most operating conditions with the exception of the out of balance tires or warped brake rotors.**

   1. Visually inspect the engine for any of the following conditions:
      - Worn, loose or slipping serpentine belt.
      - Binding or misaligned engine driven accessories: A/C Compressor, P/S Pump, Water pump, etc.
      - Improper mounting of the CKP Sensor or damaged target wheel.
      - Harmonic Balancer out of balance.
      - Extremely out of balance tires or warped brake rotors.

   Were any of the above conditions present?

   Yes

   - Repair as necessary.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 4

4. **CHECK THE ENGINE OIL LEVEL AND CONDITION**

   NOTE: **The oil level being low or the wrong oil filter or viscosity being used can cause Variable Valve Timing system operating issues. This could lead to a misfire condition.**

   NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

   - **ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION**
   - **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
   - **LOW ENGINE OIL LEVEL**

- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**
- **DETERIORATED OR DIRTY OIL**
- **CONTAMINATED ENGINE OIL**
- **INCORRECT ENGINE OIL VISCOSITY**
- **AERATED ENGINE OIL**

1. If any of the above conditions are found, repair as necessary.

   Were any of the above conditions present?

   Yes

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 5

5. **CHECK THE INTAKE SYSTEM FOR LEAKS**
   1. Check the engine and Intake Manifold for vacuum leaks.

   NOTE: **A vacuum leak can affect one or more cylinders depending on the location of the leak.**

   Were any leaks found with the intake system?

   Yes

   - Repair the leak in the intake system.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 6

6. **CHECK THE FUEL QUALITY**
   1. Check the fuel for the following:
      - Water in fuel
      - Correct type of fuel
      - Old or contaminated fuel
      - Low fuel
      - Perform the CHECK FOR PROPER ETHANOL LEVEL IN THE GASOLINE procedure. Refer to **CHECKING FOR PROPER ETHANOL LEVEL IN THE GASOLINE** .

   Were any problems found with the fuel?

   Yes

   - Replace the fuel and, if necessary, flush and clean the fuel system.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 7

7. **CHECK FOR A CLOGGED OR LEAKING FUEL INJECTOR**

NOTE: **A Fuel Injector that is plugged and spraying too little fuel, or fouled and spraying too much fuel, will generally cause a misfire during any operating condition. One faulty Fuel Injector will usually cause a single cylinder misfire. However if the injector is spraying an excessive amount of fuel, the excess fuel could also affect the adjoining cylinders. In most cases there will be far more misfire counts on the cylinder with the faulty Fuel Injector than on the other affected cylinders.**

WARNING: **The fuel system is under a constant pressure (even with the engine off). Before testing or servicing any fuel system hose, fitting or line, the fuel system pressure must be released. Failure to follow these instructions can result in possible serious or fatal injury.**

1. Install the Fuel Pressure Decay Tester (special tool #8978A, Decay Tool, Fuel) to the fuel rail.
2. Turn the ignition on and allow the fuel pressure to reach maximum pressure and stabilize.

   NOTE: **The ignition may need to be cycled off and on a couple times to reach maximum fuel pressure in the rail.**

3. Once the pressure reading has stabilized, record the fuel pressure. This is known as the "starting pressure".
4. With the scan tool, actuate the Fuel Injector for the cylinder that indicated the misfire while monitoring the fuel pressure gauge.
5. Record the fuel pressure. This is known as the "ending pressure."

   CAUTION: **After each Fuel Injector actuation, start the engine to clean the cylinder of fuel. Failure to do so could cause engine damage.**

6. Repeat sub-steps two through five with several other Fuel Injectors on cylinders that do not have a misfire. Make sure to start the Fuel Injector actuation at the same starting pressure for each injector. Compare the ending pressures of the known good cylinders to the cylinder with the misfire condition.

   Are the ending pressures about the same for all of the tested injectors?

   Yes

   - Go To 8

   No, the injector from the cylinder with the misfire stood out from the rest.

   - If the pressure drop is too small, check for debris in the Fuel Rail or Fuel Injector and repair as necessary. If the pressure drop is too large, suspect a faulty or fouled Fuel Injector as the issue.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **CHECK THE VARIABLE VALVE LIFT (VVL) SYSTEM (IF EQUIPPED)**

NOTE: **The 3.6L Upgrade engine is equipped with the VVL System. The classic engine is not. If this vehicle is not equipped with the VVL system skip this test step.**

NOTE: **A Rocker Arm or arms can get stuck due to an oil pressure issue, or a mechanical failure of a VVL Solenoid (including O-rings) or Rocker Arm. A single Rocker Arm that is stuck in low lift will not be detected and the system will continue to operate normally, however some misfire and engine roughness may be felt. One Rocker Arm stuck in Low Lift mode will cause a misfire at higher engine speeds (above approximately 4000 rpm). Two or more Rocker Arms stuck in Low Lift mode can cause a misfire at any engine speed, including idle. A Rocker Arm stuck in high lift mode typically misfires at idle.**

NOTE: **The two rear cylinders are controlled by the rear solenoid on each bank. Therefore, a VVL issue that affects both rear cylinders on a bank is most likely a common issue for both cylinders. These would include a damaged or missing O-ring, faulty solenoid, oil supply or control circuit issue. A VVL issue that only affects one of the rear cylinders is more likely going to be a failure of a Rocker Arm or pin for that cylinder.**

NOTE: **The front VVL Solenoids control the operation of the Rocker Arms for the front cylinder only on each bank. The rear VVL Solenoids control the operation of the Rocker Arms for the back two cylinders on each bank.**

1. Turn the ignition on.
2. With the scan tool, navigate to Systems Tests, perform the VVL System Diagnostic test and follow the on screen directions. for further VVL system functionality and scan tool routine information.

   NOTE: **Do not erase the DTC before running the routine.**

3. When the test is complete, compare the results to the table below for the probable failure conditions.

   Does the scan tool results show that the misfire is being caused by the VVL system?

   Yes

   - Compare the results from the routine to the table below
   -

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
Low misfire percentage on (1) Rocker Stuck Low test, (2) Rocker Stuck High, Low RPM test, and (3) Rocker Stuck High, High RPM test	No VVL issue detected	The misfire condition being detected is not caused by the VVL System. Another system is likely causing the misfire
High misfire percentage on (1) Rocker Stuck Low test, (2) Rocker Stuck High, Low RPM test, and (3) Rocker Stuck High, High RPM test	No VVL issue detected	The misfire condition being detected is not caused by the VVL System. Another system is likely causing the misfire
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 1	• VVL Solenoid 1/1 stuck on/open • VVL Solenoid 1/1 control circuit shorted to 12 volts	• Verify that the VVL Solenoid 1/1 control circuit is not shorted to 12 volts

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	• VVL Solenoid 1/1 has missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage • Cylinder 1 rocker arm lash adjuster issue (stuck or broken) • Cylinder 1 rocker arm lock pin stuck retracted • Oil pressure leakage from the supply oil passage to the front control oil passage in the Cylinder Head.	• Check operation of VVL Solenoid 1/1 for a stuck on/open condition, damaged or missing supply O-ring • Check for broken or stuck Cylinder 1 rocker arms or lock pins • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head.
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 2	• VVL Solenoid 2/1 stuck on/open • VVL Solenoid 2/1 control circuit shorted to 12 volts • VVL Solenoid 2/1 has missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage • Cylinder 2 rocker arm lash adjuster issue (stuck or broken) • Cylinder 2 rocker arm lock pin stuck retracted • Oil pressure leakage from the supply oil passage to the front control oil passage in the Cylinder Head.	• Verify that the VVL Solenoid 2/1 control circuit is not shorted to 12 volts • Check operation of VVL Solenoid 2/1 for a stuck on/open condition, damaged or missing supply O-ring • Check for broken or stuck Cylinder 2 rocker arms or lock pins • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 3	• Cylinder 3 rocker arm lash adjuster issue (stuck or broken) • Cylinder 3 rocker arm lock pin stuck retracted	• Check for broken or stuck Cylinder 3 rocker arms or lock pins
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 4	• Cylinder 4 rocker arm lash adjuster issue (stuck or broken)	• Check for broken or stuck Cylinder 4 rocker arms or lock pins

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	• Cylinder 4 rocker arm lock pin stuck retracted	
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 5	• Cylinder 5 rocker arm lash adjuster issue (stuck or broken) • Cylinder 5 rocker arm lock pin stuck retracted	• Check for broken or stuck Cylinder 5 rocker arms or lock pins
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 6	• Cylinder 6 rocker arm lash adjuster issue (stuck or broken) • Cylinder 6 rocker arm lock pin stuck retracted	• Check for broken or stuck Cylinder 6 rocker arms or lock pins
(1) Rocker Stuck Low test - high misfire percentage on Cylinder 3 and Cylinder 5	• VVL Solenoid 1/2 stuck on/open • VVL Solenoid 1/2 control circuit shorted to 12 volts • VVL Solenoid 1/2 has missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage • Oil pressure leakage from the supply oil passage to the rear control oil passage in the Cylinder Head. **NOTE:** **It's less likely but possible for a rocker arm lash adjuster failure (stuck or broken) or lock pin stuck retracted on both Cylinder 3 and Cylinder 5**	• Check the VVL Solenoid 1/2 control circuit for a short to 12 volts condition • Check operation of VVL Solenoid 1/2 for a stuck on/open condition, damaged or missing supply O-ring • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head.
(1) Rocker Stuck Low test - high misfire percentage on Cylinder 4 and Cylinder 6	• VVL Solenoid 2/2 stuck on/open • VVL Solenoid 2/2 control circuit shorted to 12 volts	• Check the VVL Solenoid 2/2 control circuit for a short to 12 volts condition

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	• VVL Solenoid 2/2 has missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage • Oil pressure leakage from the supply oil passage to the rear control oil passage in the Cylinder Head. **NOTE:** **It's less likely but possible for a rocker arm lash adjuster failure (stuck or broken) or lock pin stuck retracted on both Cylinder 4 and Cylinder 6**	• Check operation of VVL Solenoid 2/2 for a stuck on/open condition, damaged or missing supply O-ring • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - high misfire percentage Cylinder 1, Cylinder 3, and Cylinder 5	• Both bank 1 solenoids have missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage for both bank 1 solenoids • Oil pressure leakage from the supply oil passage to the front and rear control oil passages in the Cylinder Head.	• Check operation of VVL Solenoid 1/2 for a stuck on/open condition, damaged or missing supply O-ring • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - high misfire percentage Cylinder 2, Cylinder 4, and Cylinder 6	• Both bank 2 solenoids have missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control	• Check operation of VVL Solenoid 2/2 for a stuck on/open condition, damaged or missing supply O-ring

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	oil passage for both bank 2 solenoids • Oil pressure leakage from the supply oil passage to the front and rear control oil passages in the Cylinder Head.	• It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - high misfire percentage for all Cylinders (1 - 6)	• Missing or damaged supply O-rings causing oil pressure leakage from the supply oil passage to the control oil passage for front and rear solenoids on bank 1 and bank 2 • Oil pressure leakage from the supply oil passage to the front and rear control oil passages in both Cylinder Heads.	• Check operation of all VVL Solenoids for a stuck on/open condition, damaged or missing supply O-rings • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace both Cylinder Heads.
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 1	• VVL Solenoid 1/1 control circuit open or shorted to ground • VVL Solenoid 1/1 stuck closed/off • VVL Solenoid 1/1 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted • Cylinder 1 lash adjuster plugged • Cylinder 1 rocker arm lash adjuster issue (stuck or broken) • Cylinder 1 rocker arm lock pin stuck extended	• Check the VVL Solenoid 1/1 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 1/1 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 1/1 operation. Check for debris on screen • Cylinder 1 lash adjuster plugged • Cylinder 1 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High	• VVL Solenoid 2/1 stuck closed/off	• Check the VVL Solenoid 2/1 control circuit for an

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
RPM test - high misfire percentage Cylinder 2	• VVL Solenoid 2/1 control circuit open or shorted to ground • VVL Solenoid 2/1 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted • Cylinder 2 lash adjuster plugged • Cylinder 2 rocker arm lash adjuster issue (stuck or broken) • Cylinder 2 rocker arm lock pin stuck extended	open or shorted to ground condition • Check the VVL Solenoid 2/1 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 2/1 operation. Check for debris on screen • Cylinder 2 lash adjuster plugged • Cylinder 2 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 3	• Cylinder 3 lash adjuster plugged • Cylinder 3 rocker arm lash adjuster issue (stuck or broken) • Cylinder 3 rocker arm lock pin stuck extended	• Cylinder 3 lash adjuster plugged • Cylinder 3 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 4	• Cylinder 4 lash adjuster plugged • Cylinder 4 rocker arm lash adjuster issue (stuck or broken) • Cylinder 4 rocker arm lock pin stuck extended	• Cylinder 4 lash adjuster plugged • Cylinder 4 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 5	• Cylinder 5 lash adjuster plugged • Cylinder 5 rocker arm lash adjuster issue (stuck or broken) • Cylinder 5 rocker arm lock pin stuck extended	• Cylinder 5 lash adjuster plugged • Cylinder 5 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 6	• Cylinder 6 lash adjuster plugged • Cylinder 6 rocker arm lash adjuster issue (stuck or broken) • Cylinder 6 rocker arm lock pin stuck extended	• Cylinder 6 lash adjuster plugged • Cylinder 6 rocker arm stuck failure or lock pin stuck extended

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 3 and Cylinder 5	• VVL Solenoid 1/2 stuck closed/off • VVL Solenoid 1/2 control circuit open or shorted to ground • VVL Solenoid 1/2 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted **NOTE:** **It's less likely but possible for a rocker arm lash adjuster issue (stuck or broken) or lock pin stuck retracted on Cylinder 3 and Cylinder 5**	• Check the VVL Solenoid 1/2 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 1/2 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 1/2 operation. Check for debris on screen • Cylinder 3 or 5 lash adjuster plugged • Cylinder 3 or 5 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 4 and Cylinder 6	• VVL Solenoid 2/2 stuck closed/off • VVL Solenoid 2/2 control circuit open or shorted to ground • VVL Solenoid 2/2 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted **NOTE:** **It's less likely but possible for a rocker arm lash adjuster issue (stuck**	• Check the VVL Solenoid 2/2 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 2/2 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 2/2 operation. Check for debris on screen • Cylinder 4 or 6 lash adjuster plugged • Cylinder 4 or 6 rocker arm stuck failure or lock pin stuck extended

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	or broken) or lock pin stuck retracted on Cylinder 4 and Cylinder 6	
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 1, Cylinder 3 and Cylinder 5	• VVL Solenoid 1/1 and 1/2 have missing or damaged control O-rings causing oil pressure leakage from the control oil passage to the exhaust oil passage • Bank 1 oil supply passage blockage or restriction to front and rear oil feeds in the bank 1 Cylinder Head • Large internal leakage in bank 1 Cylinder Head affecting the front and rear oil feeds	• Check the control O-rings on the front and rear bank 1 VVL Solenoids for damage • Check for proper oil pressure at the front and rear bank 1 VVL Solenoids. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9. It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if the oil pressure is low to both solenoids and all other possible causes are exhausted, replace the Cylinder Head **NOTE:** **Low oil pressure in the Cylinder Head will likely also cause issues/faults for the VVT system**
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 2, Cylinder 4 and Cylinder 6	• VVL Solenoid 2/1 and 2/2 have missing or damaged control O-rings causing oil pressure leakage from the control oil passage to the exhaust oil passage • Bank 2 oil supply passage blockage or restriction to front and rear oil feeds in the bank 2 Cylinder Head	• Check the control O-rings on the front and rear bank 2 VVL Solenoids for damage • Check for proper oil pressure at the front and rear bank VVL Solenoids. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9. It is a very low

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	• Large internal leakage in bank 2 Cylinder Head affecting the front and rear oil feeds	percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if the oil pressure is low to both solenoids and all other possible causes are exhausted, replace the Cylinder Head **NOTE:** **Low oil pressure in the Cylinder Head will likely also cause issues/faults for the VVT system**
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage for all Cylinders (1 - 6)	Engine oil pressure too low to both Cylinder Heads due to: • Oil level low • Wrong viscosity oil • Oil Filter restriction • Engine mechanical failure (damaged bearings, pick-up tube or seal, engine block, etc.) • Faulty Oil Pump	• Check for proper oil level, filter and viscosity before checking engine oil pressure • If the engine oil pressure is low check for any mechanical issue that could cause low oil pressure. If there are no issues with the bearings, pick-up tube and engine block replace the Engine Oil Pump Assembly **NOTE:** **Low engine oil pressure will likely also cause issues/faults for the VVT system**

- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

No

- Go To 10

9. **CHECK THE ACTUAL OIL PRESSURE TO THE VVL SOLENOID IN THE CYLINDER HEAD**
    1. Turn the ignition off.
    2. Remove the appropriate VVL Solenoid called out by the scan tool.

3. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the VVL Solenoid.
4. Start the engine and allow it to idle.
5. With the scan tool, monitor the Dual Oil Pump mode.

NOTE: **Let the engine run long enough for the pump to switch to low pump mode.**

6. Read and record the oil pressure reading on the oil pressure gauge. Compare the reading to the main engine oil pressure reading from the Engine Oil Pressure Sensor reading on the scan tool.

NOTE: **The Cylinder Head oil pressure should be within 5.0 psi of main engine oil pressure reading.**

Is the Cylinder Head oil pressure should be within 5.0 psi of main engine oil pressure?

Yes

- Remove and inspect the screen on the VVL Solenoid for debris that can block oil flow through the solenoid. Check the seals on the VVL Solenoid for damage and proper installation. If no debris is found, and the seals appear good replace the VVL Solenoid in accordance with the Service Information.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Diagnose and repair the lack of oil pressure to the VVL Solenoid.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK FOR PROPER SPARK AT THE IGNITION COIL**
    1. Turn the ignition off and remove the Fuel Pressure Decay Tester and connect the fuel lines before continuing.

NOTE: **A faulty Ignition Coil or Spark Plug can cause a misfire at idle but could also misfire only under a heavy load on the engine. One faulty Ignition Coil or Spark Plug will usually cause a single cylinder misfire.**

2. Remove the Ignition Coil from the cylinder that is misfiring.
3. Connect the Ignition Coil harness connector.
4. Disconnect the Fuel Injector harness connector of the cylinder being tested.
5. Install a spark tester on the Ignition Coil.
6. While cranking the engine observe the spark coming from the spark tester.

Is a crisp blue spark present?

Yes

- Go To 11

No

- Go To 16

11. **INSPECT THE SPARK PLUG AND CYLINDER**
    1. Turn the ignition off.

2. Remove the Spark Plug in accordance with the Service Information.
3. Inspect the Spark Plug for the following conditions:
   - Cracks
   - Carbon Tracking
   - Fouling due to oil, coolant or excess fuel in the cylinder
   - Gap size out of specifications
   - Loose or broken electrode
4. Check for signs of oil or coolant in the cylinder.

   Were any of the above conditions present?

   Yes

   - Replace the Spark Plug. If oil or coolant were found in the cylinder or on the Spark Plug, diagnose and repair the cause.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 12

12. **CHECK THE ENGINE COMPRESSION TO CHECK FOR VALVETRAIN OR COMBUSTION CHAMBER ISSUES**

NOTE: **A cylinder compression or valvetrain issue will cause a misfire during all operating conditions. These types of failures will normally affect a single cylinder. However, depending on the type of failure incurred, other cylinders can also be affected and show misfires. In most cases there will be far more misfire counts on the cylinder with the issue than on the other affected cylinders.**

1. Perform a cylinder compression test on several cylinders and compare the known good cylinders to the cylinder that was misfiring. Refer to **CYLINDER COMPRESSION TEST** .

   Is the cylinder compression within specification?

   Yes

   - Go To 13

   No

   - Perform a Cylinder Leak Down Test to determine if the cause is from the valvetrain or combustion chamber and repair as necessary.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **EXCHANGE SPARK PLUG AND CHECK FOR MISFIRE TO FOLLOW THE SPARK PLUG**
1. Exchange the Spark Plug with a known good cylinder that was not indicating a misfire or replace the Spark Plug if it is difficult to access.
2. Start the engine and monitor the misfire monitor screen.

   Did the misfire switch to the previously good cylinder or go away if the Spark Plug was replaced?

   Yes

- Repair is complete if Spark Plug was replaced and misfire is gone, or replace the Spark Plug if it moved to the known good cylinder.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 14

14. **CLEAN THE CARBON FROM THE VALVETRAIN AND COMBUSTION CHAMBERS**

NOTE: **Carbon build up on the engine valves and guides can cause a misfire during all operating conditions but is usually more noticeable during cruising speeds or heavy engine load conditions. If carbon build up is becoming an issue it could set only a single cylinder misfire but usually will affect more than one cylinder and set multiple cylinder misfire as well.**

1. Using Mopar Combustion cleaner, de-carbon the engine.
2. After driving and clearing the combustion cleaner from the engine, erase DTCs with the scan tool.
3. Test drive the vehicle in accordance with the Freeze Frame data.
4. With the scan tool, view the Misfire Monitor.

Did the misfire return?

Yes

- Go To 15

No

- Cleaning the valves and combustion chambers repaired the fault.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

15. **CHECK THE CAMSHAFT LOBES, ROCKER ARMS AND SPRINGS**

NOTE: **Worn Camshaft Lobes, worn or broken Rocker Arms or springs may sometimes but not always be detected during a compression test. The misfire can occur at different operating conditions depending on which component is worn and the severity of the wear on the component.**

1. Visually inspect the Camshaft, Rocker Arms or springs for excessive wear or broken parts.

Were any issues found with the Camshaft, Rocker Arms or springs?

Yes

- Perform the appropriate repair in accordance with the Service Information.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 20

16. **CHECK THE ASD RELAY OUTPUT CIRCUIT**

1. Turn the ignition off.
2. Disconnect the Ignition Coil harness connector.

3. Turn the ignition on.
4. With a scan tool, actuate the ASD Relay.
5. Using a 12-volt test light connected to ground, probe the ASD Relay Output circuit at the Ignition Coil harness connector.

   Does the test light illuminate brightly?

   Yes

   - Go To 17

   No

   - Stop all scan tool actuations and repair the open or short to ground in the ASD Relay Output circuit between the PDC and Ignition Coil harness connector.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

17. **CHECK THE IGNITION COIL CONTROL CIRCUIT**

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

1. Using a 12-volt test light connected to a 12 volt source, back probe the Coil Control circuit at the Ignition Coil harness connector.
2. Crank the engine for 5 seconds while observing the test light.

   What was the condition of the test light while cranking the engine?

   Blinking brightly

   - Replace the Ignition Coil in accordance with the Service Information.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   ON constantly

   - Go To 18

   OFF constantly

   - Go To 19

18. **CHECK THE COIL CONTROL CIRCUIT FOR A SHORT TO GROUND**

1. Turn the ignition off.
2. Disconnect the PCM C2 harness connector.

   CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

3. Connect the (special tool #10436, Adapter, GPEC Diagnostic) to the engine harness side of the PCM C2 harness connector.
4. Check for continuity between ground and the Coil Control circuit at the Ignition Coil harness connector.

Is there continuity between ground and the Coil Control circuit?

Yes

- Repair the Coil Control circuit for a short to ground.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 20

19. **CHECK THE COIL CONTROL CIRCUIT FOR AN OPEN**
    1. Turn the ignition off.
    2. Measure the resistance of the Coil Control circuit between the Ignition Coil harness connector and the GPEC Adaptor.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 20

    No

    - Repair the Coil Control circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
20. **CHECK RELATED PCM AND COMPONENT HARNESS CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. With the scan tool, erase DTCs.

9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0305-CYLINDER 5 MISFIRE

THEORY OF OPERATION

The PCM uses the Crankshaft Position (CKP) Sensor to detect and monitor the Crankshaft rotational speed. Normally, the Crankshaft rotational speed is fairly stable from cylinder to cylinder. When a misfire occurs in a cylinder, the Crankshaft speed changes abruptly for that cylinder. Therefore, anything that causes a sudden change in Crankshaft speed detected for a single cylinder is determined to be an engine misfire event. A misfire fault will usually occur due to poor fuel quality or metering, lack of spark, engine timing, low engine compression due to engine mechanical or valvetrain issues, a vacuum leak or coolant leak entering the engine intake air system. Though not as common, other factors such as severe wheel balance or braking vibration, a worn serpentine belt or belt driven accessory binding should also be considered when diagnosing a misfire fault.

Depending on the engine involved, there can be several systems and components that can contribute to a misfire. **In many cases, but not always, there will be other DTCs set related to these systems. If that is the case, the focus should be on following the diagnostics for the system that has DTCs set against it.** The different components or systems will affect misfire in different ways. Factors to consider when diagnosing a misfire are whether the misfire is a single cylinder or multiple cylinder misfire, and when does the misfire occur (idle, vehicle and engine speed, heavy engine load conditions, etc.). These factors can help in determining what components or systems should be focused on during diagnostics. **Typically a multiple cylinder misfire is an indication of timing, oil or coolant consumption, air handling, fuel supply or poor fuel quality issue that can affect multiple cylinders and not a single cylinder component such as a Fuel Injector, Ignition Coil or Spark Plug.**

NOTE: **The effects that the components and systems have on misfire detection are described in more detail in the individual test steps below.**

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Fuel level above 12%.
- Battery voltage above 10.9 volts.
- The adaptive numerator has been successfully learned.
- Ambient temperature above -23B°C (-9.4B°F).
- Coolant temperature at engine start is above -7B°C (19.4B°F). If start engine temperature is below threshold, enable monitor when engine temperature reaches 21B°C (69.8B°F).

- Engine speed between approximately 400 rpm and 6200 rpm.
  - Misfire monitor is disabled during a Decel Fuel Shutoff Event (DFSO).

SET CONDITION

- The variation in crankshaft speed between cylinders exceeds a calibrated value, based on engine speed and load.

DEFAULT ACTION

- The MIL light will illuminate or flash depending on severity of the misfire.
- During a severe misfire (MIL Light flashing) the PCM will disable the Fuel Injector of the affected cylinder(s) for a calibrated number of engine revolutions to prevent damage to the Catalytic Converter. When the engine rev counter has reached the calculated threshold the Fuel Injector is turned back on. If a misfire is still occurring, the injector is disabled again. This cycle will continue until the misfire has stopped.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
ENGINE VACUUM LEAK
EXCESSIVE CARBON BUILD-UP IN CYLINDER HEAD OR COMBUSTION CHAMBER
FAULTY FUEL INJECTOR
POOR FUEL QUALITY OR HIGH ETHANOL LEVEL
CRANKSHAFT POSITION SENSOR (CKP) OR TONE WHEEL ISSUES
FAULTY IGNITION COIL OR SPARK PLUG
VARIABLE VALVE LIFT (VVL) SYSTEM ISSUES (IF EQUIPPED)
COOLANT LEAKING INTO A CYLINDER
FAULTY CYLINDER HEAD GASKET
ENGINE MECHANICAL/LOW COMPRESSION
WORN CAMSHAFT LOBES, SPRINGS OR ROCKER ARMS
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
   1. Turn the ignition on.
   2. With the scan tool, read and record all DTCs and Freeze Frame information.
   3. Operate the vehicle under conditions recorded in the Freeze Frame information when the DTC was set.

      NOTE: **During the test drive of the vehicle, note when the misfire condition is present for use later in this diagnostic test. Also monitor the Downstream O2 Sensor(s) when the misfire is occurring. O2 Sensor voltage readings that are consistently on the low side of the scale would indicate a lean condition. This could indicate a lack of fuel due to a plugged Fuel Injector or fuel system issue. O2 Sensor voltage readings that are consistently on the high side of the scale would indicate a rich condition. This could be caused by a lack of spark or a possible leaky Fuel Injector.**

NOTE: **Keep in mind that during a severe misfire (MIL Light flashing) the PCM will disable the Fuel Injector of the affected cylinder(s) for a calibrated number of engine revolutions to prevent damage to the Catalytic Converter. This can cause a misfire that occurs only at high engine speed or heavy engine load to appear to continue when returning to idle. However this could be due to the Fuel Injector being disabled until the rev counter resets.**

4. With the scan tool, view the Misfire Monitor to see which cylinders are effected.

   Are there excessive misfires shown for this cylinder at this time?

   Yes

   - Go To 2

   No

   - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are there any Service Bulletins or fuel system, ignition system component, air handling component, VVL system (if equipped), or VVT system DTCs active or pending?

      Yes

      - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

      No

      - Go To 3

3. **CHECK FOR MECHANICAL CONDITIONS THAT COULD CAUSE A MISFIRE**

   NOTE: **Each of the following conditions can cause a misfire during most operating conditions with the exception of the out of balance tires or warped brake rotors.**

   1. Visually inspect the engine for any of the following conditions:
      - Worn, loose or slipping serpentine belt.
      - Binding or misaligned engine driven accessories: A/C Compressor, P/S Pump, Water pump, etc.
      - Improper mounting of the CKP Sensor or damaged target wheel.
      - Harmonic Balancer out of balance.
      - Extremely out of balance tires or warped brake rotors.

      Were any of the above conditions present?

      Yes

      - Repair as necessary.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

- Go To 4

4. **CHECK THE ENGINE OIL LEVEL AND CONDITION**

NOTE: **The oil level being low or the wrong oil filter or viscosity being used can cause Variable Valve Timing system operating issues. This could lead to a misfire condition.**

NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

- **ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION**
- **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
- **LOW ENGINE OIL LEVEL**
- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**
- **DETERIORATED OR DIRTY OIL**
- **CONTAMINATED ENGINE OIL**
- **INCORRECT ENGINE OIL VISCOSITY**
- **AERATED ENGINE OIL**

1. If any of the above conditions are found, repair as necessary.

Were any of the above conditions present?

Yes

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 5

5. **CHECK THE INTAKE SYSTEM FOR LEAKS**

1. Check the engine and Intake Manifold for vacuum leaks.

NOTE: **A vacuum leak can affect one or more cylinders depending on the location of the leak.**

Were any leaks found with the intake system?

Yes

- Repair the leak in the intake system.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 6

6. **CHECK THE FUEL QUALITY**

1. Check the fuel for the following:
   - Water in fuel

- Correct type of fuel
- Old or contaminated fuel
- Low fuel
- Perform the CHECK FOR PROPER ETHANOL LEVEL IN THE GASOLINE procedure. Refer to **CHECKING FOR PROPER ETHANOL LEVEL IN THE GASOLINE** .

Were any problems found with the fuel?

Yes

- Replace the fuel and, if necessary, flush and clean the fuel system.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 7

7. **CHECK FOR A CLOGGED OR LEAKING FUEL INJECTOR**

NOTE: **A Fuel Injector that is plugged and spraying too little fuel, or fouled and spraying too much fuel, will generally cause a misfire during any operating condition. One faulty Fuel Injector will usually cause a single cylinder misfire. However if the injector is spraying an excessive amount of fuel, the excess fuel could also affect the adjoining cylinders. In most cases there will be far more misfire counts on the cylinder with the faulty Fuel Injector than on the other affected cylinders.**

WARNING: **The fuel system is under a constant pressure (even with the engine off). Before testing or servicing any fuel system hose, fitting or line, the fuel system pressure must be released. Failure to follow these instructions can result in possible serious or fatal injury.**

1. Install the Fuel Pressure Decay Tester (special tool #8978A, Decay Tool, Fuel) to the fuel rail.
2. Turn the ignition on and allow the fuel pressure to reach maximum pressure and stabilize.

NOTE: **The ignition may need to be cycled off and on a couple times to reach maximum fuel pressure in the rail.**

3. Once the pressure reading has stabilized, record the fuel pressure. This is known as the "starting pressure".
4. With the scan tool, actuate the Fuel Injector for the cylinder that indicated the misfire while monitoring the fuel pressure gauge.
5. Record the fuel pressure. This is known as the "ending pressure."

CAUTION: **After each Fuel Injector actuation, start the engine to clean the cylinder of fuel. Failure to do so could cause engine damage.**

6. Repeat sub-steps two through five with several other Fuel Injectors on cylinders that do not have a misfire. Make sure to start the Fuel Injector actuation at the same starting pressure for each injector. Compare the ending pressures of the known good cylinders to the cylinder with the misfire condition.

Are the ending pressures about the same for all of the tested injectors?

Yes

- Go To 8

No, the injector from the cylinder with the misfire stood out from the rest.

- If the pressure drop is too small, check for debris in the Fuel Rail or Fuel Injector and repair as necessary. If the pressure drop is too large, suspect a faulty or fouled Fuel Injector as the issue.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **CHECK THE VARIABLE VALVE LIFT (VVL) SYSTEM (IF EQUIPPED)**

NOTE: **The 3.6L Upgrade engine is equipped with the VVL System. The classic engine is not. If this vehicle is not equipped with the VVL system skip this test step.**

NOTE: **A Rocker Arm or arms can get stuck due to an oil pressure issue, or a mechanical failure of a VVL Solenoid (including O-rings) or Rocker Arm. A single Rocker Arm that is stuck in low lift will not be detected and the system will continue to operate normally, however some misfire and engine roughness may be felt. One Rocker Arm stuck in Low Lift mode will cause a misfire at higher engine speeds (above approximately 4000 rpm). Two or more Rocker Arms stuck in Low Lift mode can cause a misfire at any engine speed, including idle. A Rocker Arm stuck in high lift mode typically misfires at idle.**

NOTE: **The two rear cylinders are controlled by the rear solenoid on each bank. Therefore, a VVL issue that affects both rear cylinders on a bank is most likely a common issue for both cylinders. These would include a damaged or missing O-ring, faulty solenoid, oil supply or control circuit issue. A VVL issue that only affects one of the rear cylinders is more likely going to be a failure of a Rocker Arm or pin for that cylinder.**

NOTE: **The front VVL Solenoids control the operation of the Rocker Arms for the front cylinder only on each bank. The rear VVL Solenoids control the operation of the Rocker Arms for the back two cylinders on each bank.**

1. Turn the ignition on.
2. With the scan tool, navigate to Systems Tests, perform the VVL System Diagnostic test and follow the on screen directions. for further VVL system functionality and scan tool routine information. Refer to **VALVE TIMING, DESCRIPTION AND OPERATION** .

   NOTE: **Do not erase the DTC before running the routine.**

3. When the test is complete, compare the results to the table below for the probable failure conditions.

   Does the scan tool results show that the misfire is being caused by the VVL system?

   Yes

   - Compare the results from the routine to the table below

•

<table>
<tr><th>SCAN TOOL INTRUSIVE VVL TEST RESULT</th><th>PROBABLE CAUSES</th><th>REPAIR ACTIONS</th></tr>
<tr><td>Low misfire percentage on (1) Rocker Stuck Low test, (2) Rocker Stuck High, Low RPM test, and (3) Rocker Stuck High, High RPM test</td><td>No VVL issue detected</td><td>The misfire condition being detected is not caused by the VVL System. Another system is likely causing the misfire</td></tr>
<tr><td>High misfire percentage on (1) Rocker Stuck Low test, (2) Rocker Stuck High, Low RPM test, and (3) Rocker Stuck High, High RPM test</td><td>No VVL issue detected</td><td>The misfire condition being detected is not caused by the VVL System. Another system is likely causing the misfire</td></tr>
<tr><td>(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 1</td><td>VVL Solenoid 1/1 stuck on/open
VVL Solenoid 1/1 control circuit shorted to 12 volts
VVL Solenoid 1/1 has missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage
Cylinder 1 rocker arm lash adjuster issue (stuck or broken)
Cylinder 1 rocker arm lock pin stuck retracted
Oil pressure leakage from the supply oil passage to the front control oil passage in the Cylinder Head.</td><td>Verify that the VVL Solenoid 1/1 control circuit is not shorted to 12 volts
Check operation of VVL Solenoid 1/1 for a stuck on/open condition, damaged or missing supply O-ring
Check for broken or stuck Cylinder 1 rocker arms or lock pins
It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head.</td></tr>
<tr><td>(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 2</td><td>VVL Solenoid 2/1 stuck on/open

However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - high misfire percentage Cylinder 2, Cylinder 4, and Cylinder 6	• Both bank 2 solenoids have missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage for both bank 2 solenoids • Oil pressure leakage from the supply oil passage to the front and rear control oil passages in the Cylinder Head.	• Check operation of VVL Solenoid 2/2 for a stuck on/open condition, damaged or missing supply O-ring • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - high misfire percentage for all Cylinders (1 - 6)	• Missing or damaged supply O-rings causing oil pressure leakage from the supply oil passage to the control oil passage for front and rear solenoids on bank 1 and bank 2 • Oil pressure leakage from the supply oil passage to the front and rear control oil passages in both Cylinder Heads.	• Check operation of all VVL Solenoids for a stuck on/open condition, damaged or missing supply O-rings • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace both Cylinder Heads.
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 1	• VVL Solenoid 1/1 control circuit open or shorted to ground • VVL Solenoid 1/1 stuck closed/off • VVL Solenoid 1/1 has missing or damaged control O-ring causing	• Check the VVL Solenoid 1/1 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 1/1 for a missing or damaged control O-ring

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted • Cylinder 1 lash adjuster plugged • Cylinder 1 rocker arm lash adjuster issue (stuck or broken) • Cylinder 1 rocker arm lock pin stuck extended	• Actuate and check the VVL Solenoid 1/1 operation. Check for debris on screen • Cylinder 1 lash adjuster plugged • Cylinder 1 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 2	• VVL Solenoid 2/1 stuck closed/off • VVL Solenoid 2/1 control circuit open or shorted to ground • VVL Solenoid 2/1 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted • Cylinder 2 lash adjuster plugged • Cylinder 2 rocker arm lash adjuster issue (stuck or broken) • Cylinder 2 rocker arm lock pin stuck extended	• Check the VVL Solenoid 2/1 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 2/1 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 2/1 operation. Check for debris on screen • Cylinder 2 lash adjuster plugged • Cylinder 2 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 3	• Cylinder 3 lash adjuster plugged • Cylinder 3 rocker arm lash adjuster issue (stuck or broken) • Cylinder 3 rocker arm lock pin stuck extended	• Cylinder 3 lash adjuster plugged • Cylinder 3 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 4	• Cylinder 4 lash adjuster plugged • Cylinder 4 rocker arm lash adjuster issue (stuck or broken) • Cylinder 4 rocker arm lock pin stuck extended	• Cylinder 4 lash adjuster plugged • Cylinder 4 rocker arm stuck failure or lock pin stuck extended

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 5	• Cylinder 5 lash adjuster plugged • Cylinder 5 rocker arm lash adjuster issue (stuck or broken) • Cylinder 5 rocker arm lock pin stuck extended	• Cylinder 5 lash adjuster plugged • Cylinder 5 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 6	• Cylinder 6 lash adjuster plugged • Cylinder 6 rocker arm lash adjuster issue (stuck or broken) • Cylinder 6 rocker arm lock pin stuck extended	• Cylinder 6 lash adjuster plugged • Cylinder 6 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 3 and Cylinder 5	• VVL Solenoid 1/2 stuck closed/off • VVL Solenoid 1/2 control circuit open or shorted to ground • VVL Solenoid 1/2 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted **NOTE:** **It's less likely but possible for a rocker arm lash adjuster issue (stuck or broken) or lock pin stuck retracted on Cylinder 3 and Cylinder 5**	• Check the VVL Solenoid 1/2 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 1/2 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 1/2 operation. Check for debris on screen • Cylinder 3 or 5 lash adjuster plugged • Cylinder 3 or 5 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 4 and Cylinder 6	• VVL Solenoid 2/2 stuck closed/off • VVL Solenoid 2/2 control circuit open or shorted to ground	• Check the VVL Solenoid 2/2 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 2/2 for a missing or damaged control O-ring

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	• VVL Solenoid 2/2 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted **NOTE:** **It's less likely but possible for a rocker arm lash adjuster issue (stuck or broken) or lock pin stuck retracted on Cylinder 4 and Cylinder 6**	• Actuate and check the VVL Solenoid 2/2 operation. Check for debris on screen • Cylinder 4 or 6 lash adjuster plugged • Cylinder 4 or 6 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 1, Cylinder 3 and Cylinder 5	• VVL Solenoid 1/1 and 1/2 have missing or damaged control O-rings causing oil pressure leakage from the control oil passage to the exhaust oil passage • Bank 1 oil supply passage blockage or restriction to front and rear oil feeds in the bank 1 Cylinder Head • Large internal leakage in bank 1 Cylinder Head affecting the front and rear oil feeds	• Check the control O-rings on the front and rear bank 1 VVL Solenoids for damage • Check for proper oil pressure at the front and rear bank 1 VVL Solenoids. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9. It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if the oil pressure is low to both solenoids and all other possible causes are exhausted, replace the Cylinder Head **NOTE:** **Low oil pressure in the Cylinder Head will likely also**

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
		cause issues/faults for the VVT system
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 2, Cylinder 4 and Cylinder 6	• VVL Solenoid 2/1 and 2/2 have missing or damaged control O-rings causing oil pressure leakage from the control oil passage to the exhaust oil passage • Bank 2 oil supply passage blockage or restriction to front and rear oil feeds in the bank 2 Cylinder Head • Large internal leakage in bank 2 Cylinder Head affecting the front and rear oil feeds	• Check the control O-rings on the front and rear bank 2 VVL Solenoids for damage • Check for proper oil pressure at the front and rear bank VVL Solenoids. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9. It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if the oil pressure is low to both solenoids and all other possible causes are exhausted, replace the Cylinder Head **NOTE:** **Low oil pressure in the Cylinder Head will likely also cause issues/faults for the VVT system**
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage for all Cylinders (1 - 6)	Engine oil pressure too low to both Cylinder Heads due to: • Oil level low • Wrong viscosity oil • Oil Filter restriction • Engine mechanical failure (damaged bearings, pick-up tube or seal, engine block, etc.) • Faulty Oil Pump	• Check for proper oil level, filter and viscosity before checking engine oil pressure • If the engine oil pressure is low check for any mechanical issue that could cause low oil pressure. If there are no issues with the bearings, pick-up tube and engine block replace the Engine Oil Pump Assembly **NOTE:**

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
		Low engine oil pressure will likely also cause issues/faults for the VVT system

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 10

9. **CHECK THE ACTUAL OIL PRESSURE TO THE VVL SOLENOID IN THE CYLINDER HEAD**
    1. Turn the ignition off.
    2. Remove the appropriate VVL Solenoid called out by the scan tool.
    3. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the VVL Solenoid.
    4. Start the engine and allow it to idle.
    5. With the scan tool, monitor the Dual Oil Pump mode.

    NOTE: **Let the engine run long enough for the pump to switch to low pump mode.**

    6. Read and record the oil pressure reading on the oil pressure gauge. Compare the reading to the main engine oil pressure reading from the Engine Oil Pressure Sensor reading on the scan tool.

    NOTE: **The Cylinder Head oil pressure should be within 5.0 psi of main engine oil pressure reading.**

    Is the Cylinder Head oil pressure should be within 5.0 psi of main engine oil pressure?

    Yes

    - Remove and inspect the screen on the VVL Solenoid for debris that can block oil flow through the solenoid. Check the seals on the VVL Solenoid for damage and proper installation. If no debris is found, and the seals appear good replace the VVL Solenoid in accordance with the Service Information.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Diagnose and repair the lack of oil pressure to the VVL Solenoid.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
10. **CHECK FOR PROPER SPARK AT THE IGNITION COIL**
    1. Turn the ignition off and remove the Fuel Pressure Decay Tester and connect the fuel lines before continuing.

    NOTE: **A faulty Ignition Coil or Spark Plug can cause a misfire at idle but could also misfire only under a heavy load on the engine. One faulty**

Ignition Coil or Spark Plug will usually cause a single cylinder misfire.

2. Remove the Ignition Coil from the cylinder that is misfiring.
3. Connect the Ignition Coil harness connector.
4. Disconnect the Fuel Injector harness connector of the cylinder being tested.
5. Install a spark tester on the Ignition Coil.
6. While cranking the engine observe the spark coming from the spark tester.

Is a crisp blue spark present?

Yes

- Go To 11

No

- Go To 16

11. **INSPECT THE SPARK PLUG AND CYLINDER**
    1. Turn the ignition off.
    2. Remove the Spark Plug in accordance with the Service Information.
    3. Inspect the Spark Plug for the following conditions:
       - Cracks
       - Carbon Tracking
       - Fouling due to oil, coolant or excess fuel in the cylinder
       - Gap size out of specifications
       - Loose or broken electrode
    4. Check for signs of oil or coolant in the cylinder.

    Were any of the above conditions present?

    Yes

    - Replace the Spark Plug. If oil or coolant were found in the cylinder or on the Spark Plug, diagnose and repair the cause.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 12

12. **CHECK THE ENGINE COMPRESSION TO CHECK FOR VALVETRAIN OR COMBUSTION CHAMBER ISSUES**

    NOTE: **A cylinder compression or valvetrain issue will cause a misfire during all operating conditions. These types of failures will normally affect a single cylinder. However, depending on the type of failure incurred, other cylinders can also be affected and show misfires. In most cases there will be far more misfire counts on the cylinder with the issue than on the other affected cylinders.**

    1. Perform a cylinder compression test on several cylinders and compare the known good cylinders to the cylinder that was misfiring. Refer to **CYLINDER COMPRESSION TEST** .

    Is the cylinder compression within specification?

Yes

- Go To 13

No

- Perform a Cylinder Leak Down Test to determine if the cause is from the valvetrain or combustion chamber and repair as necessary.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **EXCHANGE SPARK PLUG AND CHECK FOR MISFIRE TO FOLLOW THE SPARK PLUG**
    1. Exchange the Spark Plug with a known good cylinder that was not indicating a misfire or replace the Spark Plug if it is difficult to access.
    2. Start the engine and monitor the misfire monitor screen.

    Did the misfire switch to the previously good cylinder or go away if the Spark Plug was replaced?

    Yes

    - Repair is complete if Spark Plug was replaced and misfire is gone, or replace the Spark Plug if it moved to the known good cylinder.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 14

14. **CLEAN THE CARBON FROM THE VALVETRAIN AND COMBUSTION CHAMBERS**

    NOTE: Carbon build up on the engine valves and guides can cause a misfire during all operating conditions but is usually more noticeable during cruising speeds or heavy engine load conditions. If carbon build up is becoming an issue it could set only a single cylinder misfire but usually will affect more than one cylinder and set multiple cylinder misfire as well.

    1. Using Mopar Combustion cleaner, de-carbon the engine.
    2. After driving and clearing the combustion cleaner from the engine, erase DTCs with the scan tool.
    3. Test drive the vehicle in accordance with the Freeze Frame data.
    4. With the scan tool, view the Misfire Monitor.

    Did the misfire return?

    Yes

    - Go To 15

    No

    - Cleaning the valves and combustion chambers repaired the fault.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

15. **CHECK THE CAMSHAFT LOBES, ROCKER ARMS AND SPRINGS**

    NOTE: Worn Camshaft Lobes, worn or broken Rocker Arms or springs may sometimes but not always be detected during a compression test. The

misfire can occur at different operating conditions depending on which component is worn and the severity of the wear on the component.

1. Visually inspect the Camshaft, Rocker Arms or springs for excessive wear or broken parts.

   Were any issues found with the Camshaft, Rocker Arms or springs?

   Yes

   - Perform the appropriate repair in accordance with the Service Information.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 20

16. **CHECK THE ASD RELAY OUTPUT CIRCUIT**
    1. Turn the ignition off.
    2. Disconnect the Ignition Coil harness connector.
    3. Turn the ignition on.
    4. With a scan tool, actuate the ASD Relay.
    5. Using a 12-volt test light connected to ground, probe the ASD Relay Output circuit at the Ignition Coil harness connector.

       Does the test light illuminate brightly?

       Yes

       - Go To 17

       No

       - Stop all scan tool actuations and repair the open or short to ground in the ASD Relay Output circuit between the PDC and Ignition Coil harness connector.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
17. **CHECK THE IGNITION COIL CONTROL CIRCUIT**

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    1. Using a 12-volt test light connected to a 12 volt source, back probe the Coil Control circuit at the Ignition Coil harness connector.
    2. Crank the engine for 5 seconds while observing the test light.

       What was the condition of the test light while cranking the engine?

       Blinking brightly

       - Replace the Ignition Coil in accordance with the Service Information.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       ON constantly

- Go To 18

OFF constantly

- Go To 19

18. **CHECK THE COIL CONTROL CIRCUIT FOR A SHORT TO GROUND**
    1. Turn the ignition off.
    2. Disconnect the PCM C2 harness connector.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    3. Connect the (special tool #10436, Adapter, GPEC Diagnostic) to the engine harness side of the PCM C2 harness connector.
    4. Check for continuity between ground and the Coil Control circuit at the Ignition Coil harness connector.

    Is there continuity between ground and the Coil Control circuit?

    Yes

    - Repair the Coil Control circuit for a short to ground.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 20

19. **CHECK THE COIL CONTROL CIRCUIT FOR AN OPEN**
    1. Turn the ignition off.
    2. Measure the resistance of the Coil Control circuit between the Ignition Coil harness connector and the GPEC Adaptor.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 20

    No

    - Repair the Coil Control circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

20. **CHECK RELATED PCM AND COMPONENT HARNESS CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.

- Corrosion.
- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0306-CYLINDER 6 MISFIRE

THEORY OF OPERATION

The PCM uses the Crankshaft Position (CKP) Sensor to detect and monitor the Crankshaft rotational speed. Normally, the Crankshaft rotational speed is fairly stable from cylinder to cylinder. When a misfire occurs in a cylinder, the Crankshaft speed changes abruptly for that cylinder. Therefore, anything that causes a sudden change in Crankshaft speed detected for a single cylinder is determined to be an engine misfire event. A misfire fault will usually occur due to poor fuel quality or metering, lack of spark, engine timing, low engine compression due to engine mechanical or valvetrain issues, a vacuum leak or coolant leak entering the engine intake air system. Though not as common, other factors such as severe wheel balance or braking vibration, a worn serpentine belt or belt driven accessory binding should also be considered when diagnosing a misfire fault.

Depending on the engine involved, there can be several systems and components that can contribute to a misfire. **In many cases, but not always, there will be other DTCs set related to these systems. If that is the case, the focus should be on following the diagnostics for the system that has DTCs set against it.** The different components or systems will affect misfire in different ways. Factors to consider when diagnosing a misfire are whether the misfire is a single cylinder or multiple cylinder misfire, and when does the misfire occur (idle, vehicle and engine speed, heavy engine load conditions, etc.). These factors can help in determining what components or systems should be focused on during diagnostics. **Typically a multiple cylinder misfire is an indication of timing, oil or coolant consumption, air handling, fuel supply or poor fuel quality issue that can affect multiple cylinders and not a single cylinder component such as a Fuel Injector, Ignition Coil or Spark Plug.**

NOTE: **The effects that the components and systems have on misfire detection are described in more detail in the individual test steps below.**

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Fuel level above 12%.
- Battery voltage above 10.9 volts.
- The adaptive numerator has been successfully learned.
- Ambient temperature above -23B°C (-9.4B°F).
- Coolant temperature at engine start is above -7B°C (19.4B°F). If start engine temperature is below threshold, enable monitor when engine temperature reaches 21B°C (69.8B°F).
- Engine speed between approximately 400 rpm and 6200 rpm.
    - Misfire monitor is disabled during a Decel Fuel Shutoff Event (DFSO).

SET CONDITION

- The variation in crankshaft speed between cylinders exceeds a calibrated value, based on engine speed and load.

DEFAULT ACTION

- The MIL light will illuminate or flash depending on severity of the misfire.
- During a severe misfire (MIL Light flashing) the PCM will disable the Fuel Injector of the affected cylinder(s) for a calibrated number of engine revolutions to prevent damage to the Catalytic Converter. When the engine rev counter has reached the calculated threshold the Fuel Injector is turned back on. If a misfire is still occurring, the injector is disabled again. This cycle will continue until the misfire has stopped.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
ENGINE VACUUM LEAK
EXCESSIVE CARBON BUILD-UP IN CYLINDER HEAD OR COMBUSTION CHAMBER
FAULTY FUEL INJECTOR
POOR FUEL QUALITY OR HIGH ETHANOL LEVEL
CRANKSHAFT POSITION SENSOR (CKP) OR TONE WHEEL ISSUES
FAULTY IGNITION COIL OR SPARK PLUG
VARIABLE VALVE LIFT (VVL) SYSTEM ISSUES (IF EQUIPPED)
COOLANT LEAKING INTO A CYLINDER
FAULTY CYLINDER HEAD GASKET
ENGINE MECHANICAL/LOW COMPRESSION
WORN CAMSHAFT LOBES, SPRINGS OR ROCKER ARMS
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. **Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .**

DIAGNOSTIC TEST

1. **CHECK FOR AN ACTIVE CONDITION**
    1. Turn the ignition on.
    2. With the scan tool, read and record all DTCs and Freeze Frame information.
    3. Operate the vehicle under conditions recorded in the Freeze Frame information when the DTC was set.

        NOTE: **During the test drive of the vehicle, note when the misfire condition is present for use later in this diagnostic test. Also monitor the Downstream O2 Sensor(s) when the misfire is occurring. O2 Sensor voltage readings that are consistently on the low side of the scale would indicate a lean condition. This could indicate a lack of fuel due to a plugged Fuel Injector or fuel system issue. O2 Sensor voltage readings that are consistently on the high side of the scale would indicate a rich condition. This could be caused by a lack of spark or a possible leaky Fuel Injector.**

        NOTE: **Keep in mind that during a severe misfire (MIL Light flashing) the PCM will disable the Fuel Injector of the affected cylinder(s) for a calibrated number of engine revolutions to prevent damage to the Catalytic Converter. This can cause a misfire that occurs only at high engine speed or heavy engine load to appear to continue when returning to idle. However this could be due to the Fuel Injector being disabled until the rev counter resets.**

    4. With the scan tool, view the Misfire Monitor to see which cylinders are effected.

        Are there excessive misfires shown for this cylinder at this time?

        Yes

        - Go To 2

        No

        - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

        Are there any Service Bulletins or fuel system, ignition system component, air handling component, VVL system (if equipped), or VVT system DTCs active or pending?

        Yes

        - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

        No

        - Go To 3
3. **CHECK FOR MECHANICAL CONDITIONS THAT COULD CAUSE A MISFIRE**

    NOTE: **Each of the following conditions can cause a misfire during most operating conditions with the exception of the out of balance tires or warped brake rotors.**

1. Visually inspect the engine for any of the following conditions:
    - Worn, loose or slipping serpentine belt.
    - Binding or misaligned engine driven accessories: A/C Compressor, P/S Pump, Water pump, etc.
    - Improper mounting of the CKP Sensor or damaged target wheel.
    - Harmonic Balancer out of balance.
    - Extremely out of balance tires or warped brake rotors.

   Were any of the above conditions present?

   Yes

    - Repair as necessary.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

    - Go To 4

4. **CHECK THE ENGINE OIL LEVEL AND CONDITION**

NOTE: **The oil level being low or the wrong oil filter or viscosity being used can cause Variable Valve Timing system operating issues. This could lead to a misfire condition.**

NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

- **ENGINE MECHANICAL TOLERANCES OUT OF SPECIFICATION**
- **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
- **LOW ENGINE OIL LEVEL**
- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**
- **DETERIORATED OR DIRTY OIL**
- **CONTAMINATED ENGINE OIL**
- **INCORRECT ENGINE OIL VISCOSITY**
- **AERATED ENGINE OIL**

1. If any of the above conditions are found, repair as necessary.

   Were any of the above conditions present?

   Yes

    - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

    - Go To 5

5. **CHECK THE INTAKE SYSTEM FOR LEAKS**

1. Check the engine and Intake Manifold for vacuum leaks.

   NOTE: **A vacuum leak can affect one or more cylinders depending on the location of the leak.**

   Were any leaks found with the intake system?

   Yes

   - Repair the leak in the intake system.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 6

6. **CHECK THE FUEL QUALITY**
   1. Check the fuel for the following:
      - Water in fuel
      - Correct type of fuel
      - Old or contaminated fuel
      - Low fuel
      - Perform the CHECK FOR PROPER ETHANOL LEVEL IN THE GASOLINE procedure. Refer to **CHECKING FOR PROPER ETHANOL LEVEL IN THE GASOLINE** .

   Were any problems found with the fuel?

   Yes

   - Replace the fuel and, if necessary, flush and clean the fuel system.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 7

7. **CHECK FOR A CLOGGED OR LEAKING FUEL INJECTOR**

   NOTE: **A Fuel Injector that is plugged and spraying too little fuel, or fouled and spraying too much fuel, will generally cause a misfire during any operating condition. One faulty Fuel Injector will usually cause a single cylinder misfire. However if the injector is spraying an excessive amount of fuel, the excess fuel could also affect the adjoining cylinders. In most cases there will be far more misfire counts on the cylinder with the faulty Fuel Injector than on the other affected cylinders.**

   WARNING: **The fuel system is under a constant pressure (even with the engine off). Before testing or servicing any fuel system hose, fitting or line, the fuel system pressure must be released. Failure to follow these instructions can result in possible serious or fatal injury.**

   1. Install the Fuel Pressure Decay Tester (special tool #8978A, Decay Tool, Fuel) to the fuel rail.
   2. Turn the ignition on and allow the fuel pressure to reach maximum pressure and stabilize.

NOTE: **The ignition may need to be cycled off and on a couple times to reach maximum fuel pressure in the rail.**

3. Once the pressure reading has stabilized, record the fuel pressure. This is known as the "starting pressure".
4. With the scan tool, actuate the Fuel Injector for the cylinder that indicated the misfire while monitoring the fuel pressure gauge.
5. Record the fuel pressure. This is known as the "ending pressure."

CAUTION: **After each Fuel Injector actuation, start the engine to clean the cylinder of fuel. Failure to do so could cause engine damage.**

6. Repeat sub-steps two through five with several other Fuel Injectors on cylinders that do not have a misfire. Make sure to start the Fuel Injector actuation at the same starting pressure for each injector. Compare the ending pressures of the known good cylinders to the cylinder with the misfire condition.

   Are the ending pressures about the same for all of the tested injectors?

   Yes

   - Go To 8

   No, the injector from the cylinder with the misfire stood out from the rest.

   - If the pressure drop is too small, check for debris in the Fuel Rail or Fuel Injector and repair as necessary. If the pressure drop is too large, suspect a faulty or fouled Fuel Injector as the issue.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **CHECK THE VARIABLE VALVE LIFT (VVL) SYSTEM (IF EQUIPPED)**

NOTE: **The 3.6L Upgrade engine is equipped with the VVL System. The classic engine is not. If this vehicle is not equipped with the VVL system skip this test step.**

NOTE: **A Rocker Arm or arms can get stuck due to an oil pressure issue, or a mechanical failure of a VVL Solenoid (including O-rings) or Rocker Arm. A single Rocker Arm that is stuck in low lift will not be detected and the system will continue to operate normally, however some misfire and engine roughness may be felt. One Rocker Arm stuck in Low Lift mode will cause a misfire at higher engine speeds (above approximately 4000 rpm). Two or more Rocker Arms stuck in Low Lift mode can cause a misfire at any engine speed, including idle. A Rocker Arm stuck in high lift mode typically misfires at idle.**

NOTE: **The two rear cylinders are controlled by the rear solenoid on each bank. Therefore, a VVL issue that affects both rear cylinders on a bank is most likely a common issue for both cylinders. These would include a damaged or missing O-ring, faulty solenoid, oil supply or control circuit issue. A VVL issue that only affects one of the rear cylinders is more likely going to be a failure of a Rocker Arm or pin for that cylinder.**

NOTE: **The front VVL Solenoids control the operation of the Rocker Arms for the front cylinder only on each bank. The rear VVL Solenoids control the operation of the Rocker Arms for the back two cylinders on each bank.**

1. Turn the ignition on.
2. With the scan tool, navigate to Systems Tests, perform the VVL System Diagnostic test and follow the on screen directions. for further VVL system functionality and scan tool routine information. Refer to VALVE TIMING, DESCRIPTION AND OPERATION .

NOTE: **Do not erase the DTC before running the routine.**

3. When the test is complete, compare the results to the table below for the probable failure conditions.

Does the scan tool results show that the misfire is being caused by the VVL system?

Yes

- Compare the results from the routine to the table below
-

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
Low misfire percentage on (1) Rocker Stuck Low test, (2) Rocker Stuck High, Low RPM test, and (3) Rocker Stuck High, High RPM test	No VVL issue detected	The misfire condition being detected is not caused by the VVL System. Another system is likely causing the misfire
High misfire percentage on (1) Rocker Stuck Low test, (2) Rocker Stuck High, Low RPM test, and (3) Rocker Stuck High, High RPM test	No VVL issue detected	The misfire condition being detected is not caused by the VVL System. Another system is likely causing the misfire
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 1	• VVL Solenoid 1/1 stuck on/open • VVL Solenoid 1/1 control circuit shorted to 12 volts • VVL Solenoid 1/1 has missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage • Cylinder 1 rocker arm lash adjuster issue (stuck or broken) • Cylinder 1 rocker arm lock pin stuck retracted • Oil pressure leakage from the supply oil passage to the front control oil passage in the Cylinder Head.	• Verify that the VVL Solenoid 1/1 control circuit is not shorted to 12 volts • Check operation of VVL Solenoid 1/1 for a stuck on/open condition, damaged or missing supply O-ring • Check for broken or stuck Cylinder 1 rocker arms or lock pins • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head.

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 2	• VVL Solenoid 2/1 stuck on/open • VVL Solenoid 2/1 control circuit shorted to 12 volts • VVL Solenoid 2/1 has missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage • Cylinder 2 rocker arm lash adjuster issue (stuck or broken) • Cylinder 2 rocker arm lock pin stuck retracted • Oil pressure leakage from the supply oil passage to the front control oil passage in the Cylinder Head.	• Verify that the VVL Solenoid 2/1 control circuit is not shorted to 12 volts • Check operation of VVL Solenoid 2/1 for a stuck on/open condition, damaged or missing supply O-ring • Check for broken or stuck Cylinder 2 rocker arms or lock pins • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 3	• Cylinder 3 rocker arm lash adjuster issue (stuck or broken) • Cylinder 3 rocker arm lock pin stuck retracted	• Check for broken or stuck Cylinder 3 rocker arms or lock pins
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 4	• Cylinder 4 rocker arm lash adjuster issue (stuck or broken) • Cylinder 4 rocker arm lock pin stuck retracted	• Check for broken or stuck Cylinder 4 rocker arms or lock pins
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 5	• Cylinder 5 rocker arm lash adjuster issue (stuck or broken) • Cylinder 5 rocker arm lock pin stuck retracted	• Check for broken or stuck Cylinder 5 rocker arms or lock pins
(1) Rocker Stuck Low test - has high misfire percentage on Cylinder 6	• Cylinder 6 rocker arm lash adjuster issue (stuck or broken) • Cylinder 6 rocker arm lock pin stuck retracted	• Check for broken or stuck Cylinder 6 rocker arms or lock pins
(1) Rocker Stuck Low test - high misfire percentage on Cylinder 3 and Cylinder 5	• VVL Solenoid 1/2 stuck on/open	• Check the VVL Solenoid 1/2 control circuit for a short to 12 volts condition

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	• VVL Solenoid 1/2 control circuit shorted to 12 volts • VVL Solenoid 1/2 has missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage • Oil pressure leakage from the supply oil passage to the rear control oil passage in the Cylinder Head. **NOTE:** **It's less likely but possible for a rocker arm lash adjuster failure (stuck or broken) or lock pin stuck retracted on both Cylinder 3 and Cylinder 5**	• Check operation of VVL Solenoid 1/2 for a stuck on/open condition, damaged or missing supply O-ring • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head.
(1) Rocker Stuck Low test - high misfire percentage on Cylinder 4 and Cylinder 6	• VVL Solenoid 2/2 stuck on/open • VVL Solenoid 2/2 control circuit shorted to 12 volts • VVL Solenoid 2/2 has missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage • Oil pressure leakage from the supply oil passage to the rear control oil passage in the Cylinder Head. **NOTE:** **It's less likely but**	• Check the VVL Solenoid 2/2 control circuit for a short to 12 volts condition • Check operation of VVL Solenoid 2/2 for a stuck on/open condition, damaged or missing supply O-ring • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	possible for a rocker arm lash adjuster failure (stuck or broken) or lock pin stuck retracted on both Cylinder 4 and Cylinder 6	Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - high misfire percentage Cylinder 1, Cylinder 3, and Cylinder 5	• Both bank 1 solenoids have missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage for both bank 1 solenoids • Oil pressure leakage from the supply oil passage to the front and rear control oil passages in the Cylinder Head.	• Check operation of VVL Solenoid 1/2 for a stuck on/open condition, damaged or missing supply O-ring • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - high misfire percentage Cylinder 2, Cylinder 4, and Cylinder 6	• Both bank 2 solenoids have missing or damaged supply O-ring causing oil pressure leakage from the supply oil passage to the control oil passage for both bank 2 solenoids • Oil pressure leakage from the supply oil passage to the front and rear control oil passages in the Cylinder Head.	• Check operation of VVL Solenoid 2/2 for a stuck on/open condition, damaged or missing supply O-ring • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace the Cylinder Head. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9.
(1) Rocker Stuck Low test - high misfire percentage for all Cylinders (1 - 6)	• Missing or damaged supply O-rings causing oil pressure leakage from the supply oil	• Check operation of all VVL Solenoids for a stuck on/open condition,

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	passage to the control oil passage for front and rear solenoids on bank 1 and bank 2 • Oil pressure leakage from the supply oil passage to the front and rear control oil passages in both Cylinder Heads.	damaged or missing supply O-rings • It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if all other possible causes are exhausted, replace both Cylinder Heads.
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 1	• VVL Solenoid 1/1 control circuit open or shorted to ground • VVL Solenoid 1/1 stuck closed/off • VVL Solenoid 1/1 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted • Cylinder 1 lash adjuster plugged • Cylinder 1 rocker arm lash adjuster issue (stuck or broken) • Cylinder 1 rocker arm lock pin stuck extended	• Check the VVL Solenoid 1/1 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 1/1 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 1/1 operation. Check for debris on screen • Cylinder 1 lash adjuster plugged • Cylinder 1 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 2	• VVL Solenoid 2/1 stuck closed/off • VVL Solenoid 2/1 control circuit open or shorted to ground • VVL Solenoid 2/1 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted • Cylinder 2 lash adjuster plugged • Cylinder 2 rocker arm lash adjuster issue (stuck	• Check the VVL Solenoid 2/1 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 2/1 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 2/1 operation. Check for debris on screen • Cylinder 2 lash adjuster plugged • Cylinder 2 rocker arm stuck failure or lock pin stuck extended

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	or broken) • Cylinder 2 rocker arm lock pin stuck extended	
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 3	• Cylinder 3 lash adjuster plugged • Cylinder 3 rocker arm lash adjuster issue (stuck or broken) • Cylinder 3 rocker arm lock pin stuck extended	• Cylinder 3 lash adjuster plugged • Cylinder 3 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 4	• Cylinder 4 lash adjuster plugged • Cylinder 4 rocker arm lash adjuster issue (stuck or broken) • Cylinder 4 rocker arm lock pin stuck extended	• Cylinder 4 lash adjuster plugged • Cylinder 4 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 5	• Cylinder 5 lash adjuster plugged • Cylinder 5 rocker arm lash adjuster issue (stuck or broken) • Cylinder 5 rocker arm lock pin stuck extended	• Cylinder 5 lash adjuster plugged • Cylinder 5 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 6	• Cylinder 6 lash adjuster plugged • Cylinder 6 rocker arm lash adjuster issue (stuck or broken) • Cylinder 6 rocker arm lock pin stuck extended	• Cylinder 6 lash adjuster plugged • Cylinder 6 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 3 and Cylinder 5	• VVL Solenoid 1/2 stuck closed/off • VVL Solenoid 1/2 control circuit open or shorted to ground • VVL Solenoid 1/2 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted **NOTE:**	• Check the VVL Solenoid 1/2 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 1/2 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 1/2 operation. Check for debris on screen • Cylinder 3 or 5 lash adjuster plugged • Cylinder 3 or 5 rocker arm stuck failure or lock pin stuck extended

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	It's less likely but possible for a rocker arm lash adjuster issue (stuck or broken) or lock pin stuck retracted on Cylinder 3 and Cylinder 5	
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 4 and Cylinder 6	• VVL Solenoid 2/2 stuck closed/off • VVL Solenoid 2/2 control circuit open or shorted to ground • VVL Solenoid 2/2 has missing or damaged control O-ring causing oil pressure leakage from the control oil passage to the exhaust oil passage • Control oil passage pressure restricted **NOTE:** **It's less likely but possible for a rocker arm lash adjuster issue (stuck or broken) or lock pin stuck retracted on Cylinder 4 and Cylinder 6**	• Check the VVL Solenoid 2/2 control circuit for an open or shorted to ground condition • Check the VVL Solenoid 2/2 for a missing or damaged control O-ring • Actuate and check the VVL Solenoid 2/2 operation. Check for debris on screen • Cylinder 4 or 6 lash adjuster plugged • Cylinder 4 or 6 rocker arm stuck failure or lock pin stuck extended
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 1, Cylinder 3 and Cylinder 5	• VVL Solenoid 1/1 and 1/2 have missing or damaged control O-rings causing oil pressure leakage from the control oil passage to the exhaust oil passage • Bank 1 oil supply passage blockage or restriction to front and	• Check the control O-rings on the front and rear bank 1 VVL Solenoids for damage • Check for proper oil pressure at the front and rear bank 1 VVL Solenoids. Proceed to step below to check the oil pressure in the

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
	rear oil feeds in the bank 1 Cylinder Head • Large internal leakage in bank 1 Cylinder Head affecting the front and rear oil feeds	Cylinder Head. Refer to 9. It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if the oil pressure is low to both solenoids and all other possible causes are exhausted, replace the Cylinder Head **NOTE:** **Low oil pressure in the Cylinder Head will likely also cause issues/faults for the VVT system**
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage Cylinder 2, Cylinder 4 and Cylinder 6	• VVL Solenoid 2/1 and 2/2 have missing or damaged control O-rings causing oil pressure leakage from the control oil passage to the exhaust oil passage • Bank 2 oil supply passage blockage or restriction to front and rear oil feeds in the bank 2 Cylinder Head • Large internal leakage in bank 2 Cylinder Head affecting the front and rear oil feeds	• Check the control O-rings on the front and rear bank 2 VVL Solenoids for damage • Check for proper oil pressure at the front and rear bank VVL Solenoids. Proceed to step below to check the oil pressure in the Cylinder Head. Refer to 9. It is a very low percentage of the time that an internal crack in a Cylinder Head would cause this issue. However if the oil pressure is low to both solenoids and all other possible causes are exhausted, replace the Cylinder Head **NOTE:** **Low oil pressure in the Cylinder Head will likely also cause**

SCAN TOOL INTRUSIVE VVL TEST RESULT	PROBABLE CAUSES	REPAIR ACTIONS
		issues/faults for the VVT system
(2) Rocker Stuck High, Low RPM test, or (3) Rocker Stuck High, High RPM test - high misfire percentage for all Cylinders (1 - 6)	Engine oil pressure too low to both Cylinder Heads due to: • Oil level low • Wrong viscosity oil • Oil Filter restriction • Engine mechanical failure (damaged bearings, pick-up tube or seal, engine block, etc.) • Faulty Oil Pump	• Check for proper oil level, filter and viscosity before checking engine oil pressure • If the engine oil pressure is low check for any mechanical issue that could cause low oil pressure. If there are no issues with the bearings, pick-up tube and engine block replace the Engine Oil Pump Assembly **NOTE:** **Low engine oil pressure will likely also cause issues/faults for the VVT system**

- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

No

- Go To 10

9. **CHECK THE ACTUAL OIL PRESSURE TO THE VVL SOLENOID IN THE CYLINDER HEAD**
    1. Turn the ignition off.
    2. Remove the appropriate VVL Solenoid called out by the scan tool.
    3. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the VVL Solenoid.
    4. Start the engine and allow it to idle.
    5. With the scan tool, monitor the Dual Oil Pump mode.

    NOTE: **Let the engine run long enough for the pump to switch to low pump mode.**

    6. Read and record the oil pressure reading on the oil pressure gauge. Compare the reading to the main engine oil pressure reading from the Engine Oil Pressure Sensor reading on the scan tool.

    NOTE: **The Cylinder Head oil pressure should be within 5.0 psi of main engine oil pressure reading.**

    Is the Cylinder Head oil pressure should be within 5.0 psi of main engine oil pressure?

    Yes

- Remove and inspect the screen on the VVL Solenoid for debris that can block oil flow through the solenoid. Check the seals on the VVL Solenoid for damage and proper installation. If no debris is found, and the seals appear good replace the VVL Solenoid in accordance with the Service Information.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Diagnose and repair the lack of oil pressure to the VVL Solenoid.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK FOR PROPER SPARK AT THE IGNITION COIL**
    1. Turn the ignition off and remove the Fuel Pressure Decay Tester and connect the fuel lines before continuing.

       NOTE: **A faulty Ignition Coil or Spark Plug can cause a misfire at idle but could also misfire only under a heavy load on the engine. One faulty Ignition Coil or Spark Plug will usually cause a single cylinder misfire.**

    2. Remove the Ignition Coil from the cylinder that is misfiring.
    3. Connect the Ignition Coil harness connector.
    4. Disconnect the Fuel Injector harness connector of the cylinder being tested.
    5. Install a spark tester on the Ignition Coil.
    6. While cranking the engine observe the spark coming from the spark tester.

    Is a crisp blue spark present?

    Yes

    - Go To 11

    No

    - Go To 16

11. **INSPECT THE SPARK PLUG AND CYLINDER**
    1. Turn the ignition off.
    2. Remove the Spark Plug in accordance with the Service Information.
    3. Inspect the Spark Plug for the following conditions:
       - Cracks
       - Carbon Tracking
       - Fouling due to oil, coolant or excess fuel in the cylinder
       - Gap size out of specifications
       - Loose or broken electrode
    4. Check for signs of oil or coolant in the cylinder.

    Were any of the above conditions present?

    Yes

    - Replace the Spark Plug. If oil or coolant were found in the cylinder or on the Spark Plug, diagnose and repair the cause.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 12

12. **CHECK THE ENGINE COMPRESSION TO CHECK FOR VALVETRAIN OR COMBUSTION CHAMBER ISSUES**

    NOTE: **A cylinder compression or valvetrain issue will cause a misfire during all operating conditions. These types of failures will normally affect a single cylinder. However, depending on the type of failure incurred, other cylinders can also be affected and show misfires. In most cases there will be far more misfire counts on the cylinder with the issue than on the other affected cylinders.**

    1. Perform a cylinder compression test on several cylinders and compare the known good cylinders to the cylinder that was misfiring. Refer to **CYLINDER COMPRESSION TEST** .

       Is the cylinder compression within specification?

       Yes

       - Go To 13

       No

       - Perform a Cylinder Leak Down Test to determine if the cause is from the valvetrain or combustion chamber and repair as necessary.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **EXCHANGE SPARK PLUG AND CHECK FOR MISFIRE TO FOLLOW THE SPARK PLUG**
    1. Exchange the Spark Plug with a known good cylinder that was not indicating a misfire or replace the Spark Plug if it is difficult to access.
    2. Start the engine and monitor the misfire monitor screen.

       Did the misfire switch to the previously good cylinder or go away if the Spark Plug was replaced?

       Yes

       - Repair is complete if Spark Plug was replaced and misfire is gone, or replace the Spark Plug if it moved to the known good cylinder.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 14

14. **CLEAN THE CARBON FROM THE VALVETRAIN AND COMBUSTION CHAMBERS**

    NOTE: **Carbon build up on the engine valves and guides can cause a misfire during all operating conditions but is usually more noticeable during cruising speeds or heavy engine load conditions. If carbon build up is becoming an issue it could set only a single cylinder misfire but usually will affect more than one cylinder and set multiple cylinder misfire as well.**

    1. Using Mopar Combustion cleaner, de-carbon the engine.

2. After driving and clearing the combustion cleaner from the engine, erase DTCs with the scan tool.
3. Test drive the vehicle in accordance with the Freeze Frame data.
4. With the scan tool, view the Misfire Monitor.

   Did the misfire return?

   Yes

   - Go To 15

   No

   - Cleaning the valves and combustion chambers repaired the fault.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

15. **CHECK THE CAMSHAFT LOBES, ROCKER ARMS AND SPRINGS**

NOTE: **Worn Camshaft Lobes, worn or broken Rocker Arms or springs may sometimes but not always be detected during a compression test. The misfire can occur at different operating conditions depending on which component is worn and the severity of the wear on the component.**

1. Visually inspect the Camshaft, Rocker Arms or springs for excessive wear or broken parts.

   Were any issues found with the Camshaft, Rocker Arms or springs?

   Yes

   - Perform the appropriate repair in accordance with the Service Information.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 20

16. **CHECK THE ASD RELAY OUTPUT CIRCUIT**

1. Turn the ignition off.
2. Disconnect the Ignition Coil harness connector.
3. Turn the ignition on.
4. With a scan tool, actuate the ASD Relay.
5. Using a 12-volt test light connected to ground, probe the ASD Relay Output circuit at the Ignition Coil harness connector.

   Does the test light illuminate brightly?

   Yes

   - Go To 17

   No

   - Stop all scan tool actuations and repair the open or short to ground in the ASD Relay Output circuit between the PDC and Ignition Coil harness connector.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

17. **CHECK THE IGNITION COIL CONTROL CIRCUIT**

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

1. Using a 12-volt test light connected to a 12 volt source, back probe the Coil Control circuit at the Ignition Coil harness connector.
2. Crank the engine for 5 seconds while observing the test light.

   What was the condition of the test light while cranking the engine?

   Blinking brightly

   - Replace the Ignition Coil in accordance with the Service Information.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   ON constantly

   - Go To 18

   OFF constantly

   - Go To 19

18. **CHECK THE COIL CONTROL CIRCUIT FOR A SHORT TO GROUND**
    1. Turn the ignition off.
    2. Disconnect the PCM C2 harness connector.

       CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    3. Connect the (special tool #10436, Adapter, GPEC Diagnostic) to the engine harness side of the PCM C2 harness connector.
    4. Check for continuity between ground and the Coil Control circuit at the Ignition Coil harness connector.

       Is there continuity between ground and the Coil Control circuit?

       Yes

       - Repair the Coil Control circuit for a short to ground.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 20

19. **CHECK THE COIL CONTROL CIRCUIT FOR AN OPEN**
    1. Turn the ignition off.
    2. Measure the resistance of the Coil Control circuit between the Ignition Coil harness connector and the GPEC Adaptor.

       Is the resistance below 3.0 Ohms?

Yes

- Go To 20

No

- Repair the Coil Control circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

20. **CHECK RELATED PCM AND COMPONENT HARNESS CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.

    5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. With the scan tool, erase DTCs.
    9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    10. With the scan tool, read DTCs.

       Did the DTC return?

       Yes

        - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

        - The wiring or poor connection problem has been repaired.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0325-KNOCK SENSOR 1 CIRCUIT

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Knock is the spontaneous auto-ignition of the remaining fuel/air mixture in the engine combustion chamber that occurs after normal combustion has started. It can occur under extreme vehicle operating conditions such as;

- excessive spark advance for the given engine operating conditions.
- high engine temperature.
- high Manifold Absolute Pressure (MAP) Sensor value.
- low humidity and heavy loads to the engine.

Severe, continuous knock may be caused by any of the following, but not limited to;

- carbon deposits.
- bad gasoline and/or low octane fuel.

Engine power is maximized when the spark advance is calibrated to the maximum torque point or the knock limited point. In order to calibrate spark advance as close as possible to its optimum point, a knock feedback system is used to protect the engine from damage.

The analog output voltage of the Knock Sensor represents the strength of the engine knock. If the engine is running, Knock Sensor voltage will not be at zero, even when knock is not present. This is due to the background noise of the engine. Background noise varies from engine to engine depending upon;

- age.
- temperature.
- speed.
- load.
- and other engine operating conditions.

An adaptive background noise curve is established by learning the knock voltage versus engine speed under non-knock conditions. When the engine is operated under high load conditions where knock is possible, the knock voltage is tested to decide if it exceeds the knock voltage threshold. Knock has occurred when the knock voltage is at or above this calibrated voltage threshold.

When knock is detected, short term spark advance is reduced by a calculated amount. The amount of spark advance reduction is based off a calibrated severity of the knock event. This reduction in spark advance is used in the next ignition event to prevent further knock events. If the knock continues, an additional reduction in short term spark advance occurs. When the knock stops, the short term reduction in spark advance is ceased. Once ceased, the long term knock compensation is reduced by a calibrated amount to recover some of the reduction in spark advance. This decreases the amount of short term spark advance reduction to optimize engine performance.

WHEN MONITORED

This diagnostic runs when the following conditions are met:

- Engine speed above 2000 rpm.
- Battery voltage between 7.5 volts and 15.8 volts.
- Barometric pressure is above 75.2 kPa.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Knock Sensor input voltage is either:

- above 4.8 volts.
- less than 0.2 volts when engine speed is above 2000 rpm.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
KNOCK SENSOR SIGNAL CIRCUIT SHORTED TO VOLTAGE
KNOCK SENSOR SIGNAL CIRCUIT OPEN
KNOCK SENSOR RETURN CIRCUIT OPEN
KNOCK SENSOR SIGNAL CIRCUIT SHORTED TO THE KNOCK SENSOR RETURN CIRCUIT
KNOCK SENSOR SIGNAL CIRCUIT SHORTED TO GROUND
KNOCK SENSOR
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to INTERMITTENT CONDITION .
2. **CHECK THE KNOCK SENSOR 1 (K42) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

Is the voltage above 5.2 volts?

Yes

- Go To 3

No

- Go To 4

3. **ISOLATE AND CHECK THE KNOCK SENSOR 1 (K42) SIGNAL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
    1. The ignition must be off when performing a resistance check to find a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
    4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

    Is there continuity between the circuit being tested and any other circuit?

    Yes

    - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 9

4. **ISOLATE AND CHECK THE KNOCK SENSOR 1 (K42) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to**

pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 5

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **ISOLATE AND CHECK THE KNOCK SENSOR 1 (K942) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

   CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 6

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **ISOLATE AND CHECK THE KNOCK SENSOR 1 (K42) SIGNAL CIRCUIT FOR A SHORT TO THE KNOCK SENSOR 1 (K942) RETURN CIRCUIT**

1. The ignition must be off when checking for a short between circuits.
2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between the circuits being tested.**

   Is there continuity between the circuits?

   Yes

   - Repair the short between the circuits.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 7

7. **ISOLATE AND CHECK THE KNOCK SENSOR 1 (K42) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.

        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

        - Go To 8

8. **REPLACE KNOCK SENSOR 1 AND RETEST FOR DTCS**
    1. Replace the component in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    2. Connect the component and Electronic Control Unit (ECU) harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs.
    5. Using the Environmental Data or When Monitored Conditions above, operate the vehicle within the conditions that set the DTC.
    6. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 9

    No

    - Replacing the faulty component repaired the fault.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.

    5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.

8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0327-KNOCK SENSOR 1 CIRCUIT LOW

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Knock is the spontaneous auto-ignition of the remaining fuel/air mixture in the engine combustion chamber that occurs after normal combustion has started. It can occur under extreme vehicle operating conditions such as;

- excessive spark advance for the given engine operating conditions.
- high engine temperature.
- high Manifold Absolute Pressure (MAP) Sensor value.
- low humidity and heavy loads to the engine.

Severe, continuous knock may be caused by any of the following, but not limited to;

- carbon deposits.
- bad gasoline and/or low octane fuel.

Engine power is maximized when the spark advance is calibrated to the maximum torque point or the knock limited point. In order to calibrate spark advance as close as possible to its optimum point, a knock feedback system is used to protect the engine from damage.

The analog output voltage of the Knock Sensor represents the strength of the engine knock. If the engine is running, Knock Sensor voltage will not be at zero, even when knock is not present. This is due to the background noise of the engine. Background noise varies from engine to engine depending upon;

- age.
- temperature.
- speed.
- load.
- and other engine operating conditions.

An adaptive background noise curve is established by learning the knock voltage versus engine speed under non-knock conditions. When the engine is operated under high load conditions where knock is possible, the knock voltage is tested to decide if it exceeds the knock voltage threshold. Knock has occurred when the knock voltage is at or above this calibrated voltage threshold.

When knock is detected, short term spark advance is reduced by a calculated amount. The amount of spark advance reduction is based off a calibrated severity of the knock event. This reduction in spark advance is used in the next ignition event to prevent further knock events. If the knock continues, an additional reduction in short term spark advance occurs. When the knock stops, the short term reduction in spark advance is ceased. Once ceased, the long term knock compensation is reduced by a calibrated amount to recover some of the reduction in spark advance. This decreases the amount of short term spark advance reduction to optimize engine performance.

WHEN MONITORED

- This diagnostic runs if the engine speed is less than or equal to 0 rpm.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Knock Sensor 1 input voltage is less than or equal to 1.0 volt with engine speed at or less than 0 rpm.

DEFAULT ACTION

- MIL light will illuminate.

POSSIBLE CAUSES

Possible Causes
KNOCK SENSOR 1 SIGNAL CIRCUIT SHORTED TO THE KNOCK SENSOR RETURN CIRCUIT
KNOCK SENSOR 1 SIGNAL CIRCUIT SHORTED TO GROUND
KNOCK SENSOR 1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

    No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **ISOLATE AND CHECK THE KNOCK SENSOR 1 (K42) SIGNAL CIRCUIT FOR A SHORT TO THE (K942) SENSOR GROUND CIRCUIT**
    1. The ignition must be off when checking for a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: **There should be no continuity between the circuits being tested.**

    Is there continuity between the circuits?

    Yes

    - Repair the short between the circuits.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 3

3. **ISOLATE AND CHECK THE KNOCK SENSOR 1 (K42) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 4

4. **REPLACE THE KNOCK SENSOR**
    1. Verify that there is good pin to terminal contact at the Knock Sensor and the Powertrain Control Module harness connector.
    2. If no problems were found in the connectors, replace the Knock Sensor 1. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    3. Reconnect the PCM C2 harness connector.
    4. Turn the ignition on.
    5. With the scan tool, erase DTCs.
    6. Start the engine and allow it to reach normal operating temperature.

WARNING:	**When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

NOTE:	**It may be necessary to test drive the vehicle within the DTC monitoring conditions in order for this DTC to reset.**

    7. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 5

    No

    - Test complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **CHECK RELATED HARNESS CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair the poor connections.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0328-KNOCK SENSOR 1 CIRCUIT HIGH

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Knock is the spontaneous auto-ignition of the remaining fuel/air mixture in the engine combustion chamber that occurs after normal combustion has started. It can occur under extreme vehicle operating conditions such as;

- excessive spark advance for the given engine operating conditions.
- high engine temperature.
- high Manifold Absolute Pressure (MAP) Sensor value.
- low humidity and heavy loads to the engine.

Severe, continuous knock may be caused by any of the following, but not limited to;

- carbon deposits.
- bad gasoline and/or low octane fuel.

Engine power is maximized when the spark advance is calibrated to the maximum torque point or the knock limited point. In order to calibrate spark advance as close as possible to its optimum point, a knock feedback system is used to protect the engine from damage.

The analog output voltage of the Knock Sensor represents the strength of the engine knock. If the engine is running, Knock Sensor voltage will not be at zero, even when knock is not present. This is due to the background noise of the engine. Background noise varies from engine to engine depending upon;

- age.
- temperature.
- speed.

- load.
- and other engine operating conditions.

An adaptive background noise curve is established by learning the knock voltage versus engine speed under non-knock conditions. When the engine is operated under high load conditions where knock is possible, the knock voltage is tested to decide if it exceeds the knock voltage threshold. Knock has occurred when the knock voltage is at or above this calibrated voltage threshold.

When knock is detected, short term spark advance is reduced by a calculated amount. The amount of spark advance reduction is based off a calibrated severity of the knock event. This reduction in spark advance is used in the next ignition event to prevent further knock events. If the knock continues, an additional reduction in short term spark advance occurs. When the knock stops, the short term reduction in spark advance is ceased. Once ceased, the long term knock compensation is reduced by a calibrated amount to recover some of the reduction in spark advance. This decreases the amount of short term spark advance reduction to optimize engine performance.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running
- Battery voltage is between 10.0 volts and 16.0 volts.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Knock Sensor 1 Signal circuit is shorted high.

DEFAULT ACTION

- The MIL light will illuminate.

POSSIBLE CAUSES

Possible Causes
KNOCK SENSOR 1 SIGNAL CIRCUIT SHORTED TO VOLTAGE
KNOCK SENSOR 1 RETURN CIRCUIT OPEN
KNOCK SENSOR 1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK THE KNOCK SENSOR 1 (K42) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Turn the ignition on.
    4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

Is there any voltage present?

Yes

- Repair the circuit for a short to voltage.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 3

3. **ISOLATE AND CHECK THE KNOCK SENSOR 1 (K942) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

    Is the resistance below 3.0 Ohms?

    Yes

- Go To 4

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE KNOCK SENSOR FOR PROPER OPERATION**
    1. Turn the ignition off.
    2. Verify that there is good pin to terminal contact at the Knock Sensor and the Powertrain Control Module harness connectors.
    3. If no problems were found in the connectors, replace the Knock Sensor. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    4. Connect the Powertrain Control Module (PCM) harness connector.
    5. Turn the ignition on.
    6. With the scan tool, erase DTCs.
    7. Start the engine and allow it to reach normal operating temperature.

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    NOTE: **It may be necessary to test drive the vehicle within the DTC monitoring conditions in order for this DTC to reset.**

    8. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 5

    No

    - Test complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **CHECK RELATED HARNESS CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.

- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Repair the poor connections.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P032F-COMBUSTION ENGINE PRODUCING INSUFFICIENT TORQUE

THEORY OF OPERATION

The Powertrain Control Module (PCM) is able to detect an engine stall event after the engine is started and certain parameters are met. The PCM will set a DTC but will not set the Malfunction Indicator Light (MIL). This allows the PCM to retain engine data from the time of the event. The DTC and saved data serves two purposes:

1. For technicians the DTC verifies that there was a stall event that was not related to an ESS system Auto-stop issue. The data saved with the DTC can be used along with any other PCM related DTCs to attempt to narrow down which system or components to focus on when diagnosing the stall event.
2. The data is automatically uploaded to an FCA database. Engineering is able to review this data to help in determining the issues that are causing the stall events and possibly aid in finding a root cause and solution. If a solution is determined for the issue, likely a Service Bulletin or Star On-line Case will be provided describing the issue, possible related symptoms and repair action.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- PCM must see engine speed over 400 RPM for minimum time of 10 seconds. This prevents a fault on an engine start/stall condition.

- Fuel level is greater then 5%.
- The PCM did not request an ESS Auto-stop event.

SET CONDITION

- The PCM detects an engine stall condition with the Immobilizer not active.

DEFAULT ACTION

- The MIL will not illuminate.

POSSIBLE CAUSES

Possible Causes
ANY CONDITION THAT CAN CAUSE AN ENGINE STALL EVENT

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR POWERTRAIN CONTROL MODULE (PCM) DTCS**
    1. With the scan tool, read PCM DTCs.

       Are there any other PCM DTCs present?

       Yes

       - Perform the applicable diagnostic procedure(s) for the other PCM DTC(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins, Star On-line Cases or Flash updates related to the DTC or stall condition.

       Are there any applicable Service Bulletins, Star On-line Cases or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Perform the START AND STALL CONDITION test procedure. Refer to **START AND STALL CONDITION** . The START AND STALL CONDITION test procedure lists several possible causes for a stall condition. This is a general list to help give direction where to look for an issue that can cause a stall. If the vehicle is setting this DTC alone with no other faults do not overlook possible intermittent circuit issues for any component or system that can cause an engine to intermittently stall. An intermittent stall event is most likely not going to be caused by an engine mechanical part issue affecting the engine combustion. Focus on electrical issues for components that can affect spark or fueling and perform the

INTERMITTENT CONDITION test procedure. Refer to **INTERMITTENT CONDITION** .

P0330-KNOCK SENSOR 2 CIRCUIT

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Knock is the spontaneous auto-ignition of the remaining fuel/air mixture in the engine combustion chamber that occurs after normal combustion has started. It can occur under extreme vehicle operating conditions such as;

- excessive spark advance for the given engine operating conditions.
- high engine temperature.
- high Manifold Absolute Pressure (MAP) Sensor value.
- low humidity and heavy loads to the engine.

Severe, continuous knock may be caused by any of the following, but not limited to;

- carbon deposits.
- bad gasoline and/or low octane fuel.

Engine power is maximized when the spark advance is calibrated to the maximum torque point or the knock limited point. In order to calibrate spark advance as close as possible to its optimum point, a knock feedback system is used to protect the engine from damage.

The analog output voltage of the Knock Sensor represents the strength of the engine knock. If the engine is running, Knock Sensor voltage will not be at zero, even when knock is not present. This is due to the background noise of the engine. Background noise varies from engine to engine depending upon;

- age.
- temperature.
- speed.
- load.
- and other engine operating conditions.

An adaptive background noise curve is established by learning the knock voltage versus engine speed under non-knock conditions. When the engine is operated under high load conditions where knock is possible, the knock voltage is tested to decide if it exceeds the knock voltage threshold. Knock has occurred when the knock voltage is at or above this calibrated voltage threshold.

When knock is detected, short term spark advance is reduced by a calculated amount. The amount of spark advance reduction is based off a calibrated severity of the knock event. This reduction in spark advance is used in the next ignition event to prevent further knock events. If the knock continues, an additional reduction in short term spark advance occurs. When the knock stops, the short term reduction in spark advance is ceased. Once ceased, the long term knock compensation is reduced by a calibrated amount to recover some of the reduction in spark advance. This decreases the amount of short term spark advance reduction to optimize engine performance.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Engine speed above 2000 rpm.
- Battery voltage between 7.5 volts and 15.8 volts.
- Barometric pressure is above 75.2 kPa.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Knock Sensor input voltage is either:
  - Above 4.8 volts.
  - Less than 0.2 volts when engine speed is above 2000 rpm.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
KNOCK SENSOR 2 SIGNAL CIRCUIT SHORTED TO VOLTAGE
KNOCK SENSOR 2 SIGNAL CIRCUIT OPEN
KNOCK SENSOR 2 RETURN CIRCUIT OPEN
KNOCK SENSOR 2 SIGNAL CIRCUIT SHORTED TO THE KNOCK SENSOR 2 RETURN CIRCUIT
KNOCK SENSOR 2 SIGNAL CIRCUIT SHORTED TO GROUND
KNOCK SENSOR
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR DTC TO RETURN**
   1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
   2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
   3. With the scan tool, erase all DTCs.
   4. Turn the ignition off for a minimum of 10.0 seconds.
   5. Turn the ignition on.
   6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
   7. With the scan tool, read DTCs.

   Did the DTC return?

   Yes

   - Go To 2

   No

   - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECK THE KNOCK SENSOR 2 (K242) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
   1. Turn the ignition off.
   2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Turn the ignition on.

4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

NOTE: **The voltage on a 5.0 volt signal or reference circuit should be between approximately 4.8 and 5.2 volts.**

Is the voltage above 5.2 volts?

Yes

- Go To 3

No

- Go To 4

3. **ISOLATE AND CHECK THE KNOCK SENSOR 2 (K242) SIGNAL CIRCUIT FOR A SHORT TO ANOTHER CIRCUIT AT THE PCM HARNESS CONNECTOR**
   1. The ignition must be off when performing a resistance check to find a short between circuits.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. At this time leave all in-line connectors connected. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect one lead of the DVOM to the circuit being tested at the ECU harness connector.
   4. With the other lead of the DVOM probe all other circuits at the ECU harness connector.
   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **With the circuit isolated there should be no continuity between the circuit being tested and any other circuit.**

   Is there continuity between the circuit being tested and any other circuit?

   Yes

   - Repair the short between the circuits that have continuity. Use the appropriate wiring diagram as a guide to trace the circuits and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

4. **ISOLATE AND CHECK THE KNOCK SENSOR 2 (K242) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

Is the resistance below 3.0 Ohms?

Yes

- Go To 5

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **ISOLATE AND CHECK THE KNOCK SENSOR 2 (K924) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

Is the resistance below 3.0 Ohms?

Yes

- Go To 6

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **ISOLATE AND CHECK THE KNOCK SENSOR 2 (K242) SIGNAL CIRCUIT FOR A SHORT TO THE KNOCK SENSOR 2 (K924) RETURN CIRCUIT**
    1. The ignition must be off when checking for a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

    CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: There should be no continuity between the circuits being tested.

    Is there continuity between the circuits?

    Yes

    - Repair the short between the circuits.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

    No

    - Go To 7
7. **ISOLATE AND CHECK THE KNOCK SENSOR 2 (K242) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

    CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

    NOTE: There should be no continuity between ground and the circuit being tested.

    Is there continuity between ground and the circuit being tested?

    Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 8

8. **REPLACE KNOCK SENSOR 2 AND RETEST FOR DTCS**
    1. Replace the component in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    2. Connect the component and Electronic Control Unit (ECU) harness connectors.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs.
    5. Using the Environmental Data or When Monitored Conditions above, operate the vehicle within the conditions that set the DTC.
    6. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 9

    No

    - Replacing the faulty component repaired the fault.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.

7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
    - Test complete.

P0332-KNOCK SENSOR 2 CIRCUIT LOW

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Knock is the spontaneous auto-ignition of the remaining fuel/air mixture in the engine combustion chamber that occurs after normal combustion has started. It can occur under extreme vehicle operating conditions such as;

- excessive spark advance for the given engine operating conditions.
- high engine temperature.
- high Manifold Absolute Pressure (MAP) Sensor value.
- low humidity and heavy loads to the engine.

Severe, continuous knock may be caused by any of the following, but not limited to;

- carbon deposits.
- bad gasoline and/or low octane fuel.

Engine power is maximized when the spark advance is calibrated to the maximum torque point or the knock limited point. In order to calibrate spark advance as close as possible to its optimum point, a knock feedback system is used to protect the engine from damage.

The analog output voltage of the Knock Sensor represents the strength of the engine knock. If the engine is running, Knock Sensor voltage will not be at zero, even when knock is not present. This is due to the background noise of the engine. Background noise varies from engine to engine depending upon;

- age.
- temperature.
- speed.
- load.
- and other engine operating conditions.

An adaptive background noise curve is established by learning the knock voltage versus engine speed under non-knock conditions. When the engine is operated under high load conditions where knock is possible, the knock voltage is tested to decide if it exceeds the knock voltage threshold. Knock has occurred when the knock voltage is at or above this calibrated voltage threshold.

When knock is detected, short term spark advance is reduced by a calculated amount. The amount of spark advance reduction is based off a calibrated severity of the knock event. This reduction in spark advance is used in the next ignition event to prevent further knock events. If the knock continues, an additional reduction in short term spark advance occurs. When the knock stops, the short term reduction in spark advance is ceased. Once ceased, the long term knock compensation is reduced by a calibrated amount to recover some of the reduction in spark advance. This decreases the amount of short term spark advance reduction to optimize engine performance.

WHEN MONITORED

- This diagnostic runs if the engine speed is less than or equal to 0 rpm.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Knock Sensor 2 input voltage is less than or equal to 1.0 volt with engine speed at or less than 0 rpm.

DEFAULT ACTION

- MIL light will illuminate.

POSSIBLE CAUSES

Possible Causes
KNOCK SENSOR SIGNAL 2 CIRCUIT SHORTED TO THE KNOCK SENSOR RETURN CIRCUIT
KNOCK SENSOR SIGNAL 2 CIRCUIT SHORTED TO GROUND
KNOCK SENSOR 2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **ISOLATE AND CHECK THE KNOCK SENSOR 2 (K242) SIGNAL CIRCUIT FOR A SHORT TO THE (K924) SENSOR GROUND CIRCUIT**
    1. The ignition must be off when checking for a short between circuits.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the test leads of the DVOM and check for continuity between the circuits being tested at the component harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **There should be no continuity between the circuits being tested.**

Is there continuity between the circuits?

Yes

- Repair the short between the circuits.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 3

3. **ISOLATE AND CHECK THE KNOCK SENSOR 2 (K242) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 4

4. **REPLACE THE KNOCK SENSOR**
    1. Verify that there is good pin to terminal contact at the Knock Sensor and the Powertrain Control Module harness connector.
    2. If no problems were found in the connectors, replace the Knock Sensor 2. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
    3. Reconnect the PCM C2 harness connector.
    4. Turn the ignition on.
    5. With the scan tool, erase DTCs.
    6. Start the engine and allow it to reach normal operating temperature.

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    NOTE: **It may be necessary to test drive the vehicle within the DTC monitoring conditions in order for this DTC to reset.**

    7. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 5

    No

    - Test complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **CHECK RELATED HARNESS CONNECTIONS**
    1. Disconnect all PCM harness connectors.
    2. Disconnect all related in-line harness connections (if equipped).
    3. Disconnect the related component harness connectors.
    4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair the poor connections.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0333-KNOCK SENSOR 2 CIRCUIT HIGH

For a complete INTAKE AIR SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

Knock is the spontaneous auto-ignition of the remaining fuel/air mixture in the engine combustion chamber that occurs after normal combustion has started. It can occur under extreme vehicle operating conditions such as;

- excessive spark advance for the given engine operating conditions.
- high engine temperature.
- high Manifold Absolute Pressure (MAP) Sensor value.
- low humidity and heavy loads to the engine.

Severe, continuous knock may be caused by any of the following, but not limited to;

- carbon deposits.
- bad gasoline and/or low octane fuel.

Engine power is maximized when the spark advance is calibrated to the maximum torque point or the knock limited point. In order to calibrate spark advance as close as possible to its optimum point, a knock feedback system is used to protect the engine from damage.

The analog output voltage of the Knock Sensor represents the strength of the engine knock. If the engine is running, Knock Sensor voltage will not be at zero, even when knock is not present. This is due to the background noise of the engine. Background noise varies from engine to engine depending upon;

- age.
- temperature.
- speed.

- load.
- and other engine operating conditions.

An adaptive background noise curve is established by learning the knock voltage versus engine speed under non-knock conditions. When the engine is operated under high load conditions where knock is possible, the knock voltage is tested to decide if it exceeds the knock voltage threshold. Knock has occurred when the knock voltage is at or above this calibrated voltage threshold.

When knock is detected, short term spark advance is reduced by a calculated amount. The amount of spark advance reduction is based off a calibrated severity of the knock event. This reduction in spark advance is used in the next ignition event to prevent further knock events. If the knock continues, an additional reduction in short term spark advance occurs. When the knock stops, the short term reduction in spark advance is ceased. Once ceased, the long term knock compensation is reduced by a calibrated amount to recover some of the reduction in spark advance. This decreases the amount of short term spark advance reduction to optimize engine performance.

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running
- Battery voltage is between 10.0 volts and 16.0 volts.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Knock Sensor 2 Signal circuit is shorted high.

DEFAULT ACTION

- The MIL light will illuminate.

POSSIBLE CAUSES

Possible Causes
KNOCK SENSOR SIGNAL 2 CIRCUIT SHORTED TO VOLTAGE
KNOCK SENSOR RETURN 2 CIRCUIT OPEN
KNOCK SENSOR 2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK THE KNOCK SENSOR 2 (K242) SIGNAL CIRCUIT FOR A SHORT TO VOLTAGE**
   1. Turn the ignition off.
   2. Disconnect the harness connector at the component of the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Turn the ignition on.
   4. Using a DVOM, measure the voltage of the circuit being tested at the component harness connector.

   Is there any voltage present?

   Yes

   - Repair the circuit for a short to voltage.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 3

3. **ISOLATE AND CHECK THE KNOCK SENSOR 2 (K924) RETURN CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

   CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

      NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

      Is the resistance below 3.0 Ohms?

      Yes

- Go To 4

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE KNOCK SENSOR FOR PROPER OPERATION**
   1. Turn the ignition off.
   2. Verify that there is good pin to terminal contact at the Knock Sensor and the Powertrain Control Module harness connectors.
   3. If no problems were found in the connectors, replace the Knock Sensor 2. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** .
   4. Connect the Powertrain Control Module (PCM) harness connector.
   5. Turn the ignition on.
   6. With the scan tool, erase DTCs.
   7. Start the engine and allow it to reach normal operating temperature.

      WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

      NOTE: **It may be necessary to test drive the vehicle within the DTC monitoring conditions in order for this DTC to reset.**

   8. With the scan tool, read DTCs.

   Is the DTC active or pending?

   Yes

   - Go To 5

   No

   - Test complete.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

5. **CHECK RELATED HARNESS CONNECTIONS**
   1. Disconnect all PCM harness connectors.
   2. Disconnect all related in-line harness connections (if equipped).
   3. Disconnect the related component harness connectors.
   4. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.

- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

5. Connect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
6. Connect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
7. Connect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. With the scan tool, erase DTCs.
9. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
10. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair the poor connections.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0335-CRANKSHAFT POSITION SENSOR CIRCUIT

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Powertrain Control Module (PCM) uses the Crankshaft Position (CKP) Sensor signal and the Camshaft Position (CMP) Sensor signal together to identify engine timing/firing order. This process is done by recognizing the patterns of each signal. From those patterns an engine position can be determined. This process is described as engine synchronization.

- The CKP Sensor contains an Integrated Circuit (IC) and a magnet. The sensor outputs a digital signal based on the magnetic flux changes of the magnet created from the teeth and valleys of the tone wheel located on the Crankshaft or Flex Plate depending on engine. The PCM identifies the Crankshaft position angle by recognizing the reference tooth/gap. The reference tooth or gap is the largest feature of the tone wheel. This identification process is said to "lock" the crank signal.
- The PCM determines the Camshaft position angle in a similar way. By recognizing unique but successive features on the Camshaft tone wheel, the PCM can identify the particular angle at which the camshaft signal is indicating. Upon recognition of the Camshaft signal pattern sequence, it is also said to be "locked".

When both locked conditions have been met, the engine is said to be synchronized. At this time, sequencing the ignition timing and fuel injection events for the engine can begin. From the CKP signal, engine speed and misfire detection are also determined. When the PCM loses pattern recognition of the CKP signal, it is said to be "unlocked". The PCM will try to re-establish pattern recognition. If the PCM fails to achieve the pattern recognition, or if the CKP Signal unlocks more than a calibrated number of times within a calibrated threshold of time, a code is set.

NOTE: **The engine may still start even if either the CKP or CMP fails. The PCM eventually sorts out engine position and can start the vehicle on just one of these two inputs. However, there is a delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

WHEN MONITORED

- This diagnostic runs continuously with the engine cranking and with the engine running.

SET CONDITION

There are two conditions in which this DTC can set:

- **During cranking:** The CKP Sensor signal is unable to be locked for more than approximately 2.5 seconds after the CMP Sensor signal is locked.
- **Engine running:** The PCM loses the CKP position (unlocks) and fails to re-lock within approximately 0.15 seconds.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
CRANKSHAFT POSITION SENSOR MOUNTED INCORRECTLY OR MOUNTING SURFACE DAMAGED
5-VOLT SUPPLY CIRCUIT OPEN/HIGH RESISTANCE
CKP SENSOR POSITION SIGNAL CIRCUIT SHORTED TO VOLTAGE
CKP SENSOR POSITION SIGNAL CIRCUIT SHORTED TO GROUND
CKP SENSOR POSITION SIGNAL CIRCUIT SHORTED TO THE CKP SENSOR GROUND CIRCUIT
CKP SENSOR POSITION SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
CKP SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CRANKSHAFT POSITION SENSOR
TONE WHEEL/PULSE RING
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

Yes

- Perform the applicable repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 2

2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 5

    No

    - Go To 3

3. **WIRE HARNESS/CKP SENSOR INSPECTION**
    1. Turn the ignition off.
    2. Verify that the CKP Sensor harness connector is fully seated and the primary lock is engaged at the sensor before disconnecting.
    3. Start the engine and wiggle test the wiring harness and connectors in attempt to duplicate the problem.
    4. Turn the ignition off.
    5. Disconnect the harness connectors at the PCM and Crank Sensor and inspect for wire chaffing or rub conditions, terminals pushed out on the wiring connector, bent terminals at the PCM and Crank Sensor, water in the connector cavities, presence of corrosion on the terminals of the connectors or components.
    6. Visually inspect the mounting area of Crank Sensor for debris/damage or a loose sensor.

    Were any problems found?

    Yes

    - Perform the appropriate repair.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 4

4. **CHECK THE VEHICLES REPAIR HISTORY**
    1. Check the history of the vehicle for previous Crank Sensor related DTCs within the past 90 days. Verify if the Crank Sensor was replaced during the previous visit.

       Did the repair history show that the vehicle was serviced for a crank sensor fault within the past 30 days?

       Yes, and the Crank Sensor was replaced on previous visit

       - Wiggle test the wiring harness and connectors again and try to duplicate the issue. If unable to duplicate, remove the Crank Sensor and visually inspect the sensor mounting location for damage or foreign material.
       - Inspect the target wheel for any signs of damage by placing a bore scope into the CKP Sensor bore and manually rotate the engine slowly using a wrench on the crank damper bolt. For stamped steel targets, pay close attention to the light reflection of the bore scope light on each tooth. If a tooth is bent, the reflection (bright spot) will move in relation to the reflection of the other teeth that are not bent. The light reflection will remain in the same location on each tooth if none of the teeth are bent. For powder metal targets, look for any tooth that is dull or does not shine as compared to the other teeth. The rough surface that remains from a tooth that has broken off appears to be dull/non-reflective.
       - Repair as necessary. With the scan tool, perform the Cam/Crank Relearn Procedure. The Cam/Crank Relearn Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       Yes, and the Crank Sensor was not replaced on the last visit

       - Replace the Crank Sensor in accordance with the Service Information. With the scan tool, perform the Cam/Crank Relearn Procedure. The Cam/Crank Relearn Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Test complete. Reconnect the harness connectors and erase the DTC. The most likely cause was a poor connection at one of the harness connectors.
5. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

       Are there any 5-Volt Reference DTCs present?

       Yes

       - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 6
6. **CHECK THE (F855) 5-VOLT SUPPLY CIRCUIT VOLTAGE**
    1. Turn the ignition off.

2. Disconnect the CKP Sensor harness connector.
3. Turn the ignition on.
4. Measure the voltage on the (F855) 5-Volt Supply circuit at the CKP Sensor harness connector.

   Is the voltage between 4.8 and 5.2 volts?

   Yes

   - Go To 7

   No, voltage is below 4.8 volts:

   - Repair the 5-Volt Supply circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No, voltage is above 5.2 volts:

   - Repair the 5-Volt Supply circuit for a short to voltage.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **CHECK THE CKP (K24) SIGNAL CIRCUIT VOLTAGE**
   1. Measure the voltage on the CKP (K24) Signal circuit at the CKP Sensor harness connector.

      Is the voltage between 4.8 and 5.2 volts?

      Yes

      - Go To 8

      No

      - Go To 10
8. **CHECK THE (K925) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.
   3. Measure the resistance of the (K925) Sensor Ground circuit between the CKP Sensor harness connector and the PCM C2 harness connector.

      Is the resistance below 3.0 Ohms?

      Yes

      - Go To 9

      No

      - Repair the (K925) Sensor Ground circuit for an open or high resistance.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
9. **VISUALLY INSPECT THE TARGET WHEEL/PULSE RING FOR DAMAGE OR EXCESSIVE RUNOUT**
   1. Disconnect the battery ground cable.
   2. Remove the CKP Sensor.
   3. Visually inspect the sensor mounting location for damage, foreign material.

4. Rotate the engine and if possible inspect the Target Wheel for any signs of damage.
5. Inspect the target wheel for any signs of damage by placing a bore scope into the CKP Sensor bore and manually rotate the engine slowly using a wrench on the crank damper bolt. For stamped steel targets, pay close attention to the light reflection of the bore scope light on each tooth. If a tooth is bent, the reflection (bright spot) will move in relation to the reflection of the other teeth that are not bent. The light reflection will remain in the same location on each tooth if none of the teeth are bent. For powder metal targets, look for any tooth that is dull or does not shine as compared to the other teeth. The rough surface that remains from a tooth that has broken off appears to be dull/non-reflective.

   Were any problems found?

   Yes

   - Repair Issues in mounting location, or repair or replace the Target Wheel/Pulse Ring as necessary. With the scan tool, perform the Cam/Crank Relearn Procedure. The Cam/Crank Relearn Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Replace the Crank Position Sensor in accordance with the Service Information. With the scan tool, perform the Cam/Crank Relearn Procedure. The Cam/Crank Relearn Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

10. **CHECK THE CKP (K24) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. Turn the ignition off.
    2. Disconnect the PCM C2 harness connector.
    3. Check for continuity between ground and the CKP (K24) Signal circuit at the CKP Sensor harness connector.

       Is there continuity between ground and the CKP (K24) Signal circuit?

       Yes

       - Repair the CKP (K24) Signal circuit for a short to ground.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 11
11. **CHECK THE CKP (K24) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. Measure the resistance of the CKP (K24) Signal circuit between the CKP Sensor harness connector and the PCM C2 harness connector.

       Is the resistance below 3.0 Ohms?

       Yes

- Go To 12

No

- Repair the CKP (K24) Signal circuit for an open circuit or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

12. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0339-CRANKSHAFT POSITION SENSOR INTERMITTENT

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Powertrain Control Module (PCM) uses the Crankshaft Position (CKP) Sensor signal and the Camshaft Position (CMP) Sensor signal together to identify engine timing/firing order. This process is done by recognizing the patterns of each signal. From those patterns an engine position can be determined. This process is described as engine synchronization.

- The CKP Sensor contains an Integrated Circuit (IC) and a magnet. The sensor outputs a digital signal based on the magnetic flux changes of the magnet created from the teeth and valleys of the tone wheel located on the Crankshaft or Flex Plate depending on engine. The PCM identifies the Crankshaft position angle by recognizing the reference tooth/gap. The reference tooth or gap is the largest feature of the tone wheel. This identification process is said to "lock" the crank signal.
- The PCM determines the Camshaft position angle in a similar way. By recognizing unique but successive features on the Camshaft tone wheel, the PCM can identify the particular angle at which the camshaft signal is indicating. Upon recognition of the Camshaft signal pattern sequence, it is also said to be "locked".

When both locked conditions have been met, the engine is said to be synchronized. At this time, sequencing the ignition timing and fuel injection events for the engine can begin. From the CKP signal, engine speed and misfire detection are also determined. When the PCM loses pattern recognition of the CKP signal, it is said to be "unlocked". The PCM will try to re-establish pattern recognition. If the PCM fails to achieve the pattern recognition, or if the CKP Signal unlocks more than a calibrated number of times within a calibrated threshold of time, a code is set.

NOTE: **The engine may still start even if either the CKP or CMP fails. The PCM eventually sorts out engine position and can start the vehicle on just one of these two inputs. However, there is a delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

WHEN MONITORED

- This diagnostic runs continuously with the engine cranking and with the engine running.

SET CONDITION

- The PCM detects a calibrated number of "unlock" events of the CKP Sensor signal within a calibrated threshold of test time.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
5-VOLT SUPPLY CIRCUIT SHORTED TO THE CKP SENSOR GROUND CIRCUIT
5-VOLT SUPPLY CIRCUIT OPEN/HIGH RESISTANCE
CKP SENSOR POSITION SIGNAL CIRCUIT SHORTED TO VOLTAGE
CKP SENSOR POSITION SIGNAL CIRCUIT SHORTED TO GROUND
CKP SENSOR POSITION SIGNAL CIRCUIT SHORTED TO THE CKP SENSOR GROUND CIRCUIT

Possible Causes
CKP SENSOR POSITION SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
CKP SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CRANKSHAFT POSITION SENSOR MOUNTED INCORRECTLY OR MOUNTING SURFACE DAMAGED
TARGET WHEEL/PULSE RING BENT / BROKEN / MISSING TEETH / EXCESSIVE RUNOUT
CRANKSHAFT POSITION SENSOR
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK FOR ANY SERVICE BULLETINS OR PCM SOFTWARE UPDATES**
    1. Check for any applicable Service Bulletins or Flash updates related to the DTC.

       Are there any applicable Service Bulletins or Flash updates?

       Yes

       - Perform the applicable repair.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 2
2. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

       Did the DTC return?

       Yes

       - Go To 5

       No

       - Go To 3
3. **WIRE HARNESS/CKP SENSOR INSPECTION**
    1. Turn the ignition off.
    2. Verify that the CKP Sensor harness connector is fully seated and the primary lock is engaged at the sensor before disconnecting.

3. Start the engine and wiggle test the wiring harness and connectors in attempt to duplicate the problem.
4. Turn the ignition off.
5. Disconnect the harness connectors at the PCM and Crank Sensor and inspect for wire chaffing or rub conditions, terminals pushed out on the wiring connector, bent terminals at the PCM and Crank Sensor, water in the connector cavities, presence of corrosion on the terminals of the connectors or components.
6. Visually inspect the mounting area of Crank Sensor for debris/damage or a loose sensor.

   Were any problems found?

   Yes

   - Perform the appropriate repair.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 4

4. **CHECK THE VEHICLES REPAIR HISTORY**
   1. Check the history of the vehicle for previous Crank Sensor related DTCs within the past 30 days. Verify if the Crank Sensor was replaced during the visit.

      Did the repair history show that the vehicle was in dealership for a crank sensor fault within the past 30 days?

      Yes, and the Crank Sensor was replaced on previous visit

      - Wiggle test the wiring harness and connectors again and try to duplicate the issue. If not able to duplicate, remove the Crank Sensor, and visually inspect the sensor mounting location for damage, foreign material.
      - Inspect the target wheel for any signs of damage by placing a bore scope into the CKP Sensor bore and manually rotate the engine slowly using a wrench on the crank damper bolt. For stamped steel targets, pay close attention to the light reflection of the bore scope light on each tooth. If a tooth is bent, the reflection (bright spot) will move in relation to the reflection of the other teeth that are not bent. The light reflection will remain in the same location on each tooth if none of the teeth are bent. For powder metal targets, look for any tooth that is dull or does not shine as compared to the other teeth. The rough surface that remains from a tooth that has broken off appears to be dull/non-reflective.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      Yes, and the Crank Sensor was not replaced on the last visit

      - Replace the Crank Sensor in accordance with the Service Information. With the scan tool, perform the Cam/Crank Relearn Procedure. The Cam/Crank Relearn Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

- Test complete. Reconnect the harness connectors and erase the DTC. The most likely cause was a poor connection at one of the harness connectors.

5. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

    Are there any 5-Volt Reference DTCs present?

    Yes

    - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

    No

    - Go To 6

6. **CHECK THE (F855) 5-VOLT SUPPLY CIRCUIT VOLTAGE**
    1. Turn the ignition off.
    2. Disconnect the CKP Sensor harness connector.
    3. Turn the ignition on.
    4. Measure the voltage on the (F855) 5-Volt Supply circuit at the CKP Sensor harness connector.

    Is the voltage between 4.8 and 5.2 volts?

    Yes

    - Go To 7

    No, voltage is below 4.8 volts:

    - Repair the 5-Volt Supply circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No, voltage is above 5.2 volts:

    - Repair the 5-Volt Supply circuit for a short to voltage.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **CHECK THE CKP (K24) SIGNAL CIRCUIT VOLTAGE**
    1. Measure the voltage on the CKP (K24) Signal circuit at the CKP Sensor harness connector.

    Is the voltage between 4.8 and 5.2 volts?

    Yes

    - Go To 8

    No, voltage is below 5.2 volts:

    - Go To 10

    No, voltage is above 5.2 volts:

    - Repair the 5-Volt Supply circuit for a short to voltage.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **CHECK THE (K925) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. Turn the ignition off.
    2. Disconnect the PCM C2 harness connector.
    3. Measure the resistance of the (K925) Sensor Ground circuit between the CKP Sensor harness connector and the PCM C2 harness connector.

       Is the resistance below 3.0 Ohms?

       Yes

       - Go To 9

       No

       - Repair the (K925) Sensor Ground circuit for an open or high resistance.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
9. **VISUALLY INSPECT THE TARGET WHEEL/PULSE RING FOR DAMAGE OR EXCESSIVE RUNOUT**
    1. Disconnect the battery ground cable.
    2. Remove the CKP Sensor.
    3. Visually inspect the sensor mounting location for damage, foreign material.
    4. Rotate the engine and if possible inspect the Target Wheel for any signs of damage.
    5. Inspect the target wheel for any signs of damage by placing a bore scope into the CKP Sensor bore and manually rotate the engine slowly using a wrench on the crank damper bolt. For stamped steel targets, pay close attention to the light reflection of the bore scope light on each tooth. If a tooth is bent, the reflection (bright spot) will move in relation to the reflection of the other teeth that are not bent. The light reflection will remain in the same location on each tooth if none of the teeth are bent. For powder metal targets, look for any tooth that is dull or does not shine as compared to the other teeth. The rough surface that remains from a tooth that has broken off appears to be dull/non-reflective.

       Were any problems found?

       Yes

       - Repair Issues in mounting location, or repair or replace the Target Wheel / Pulse Ring as necessary. With the scan tool, perform the Cam/Crank Relearn Procedure. The Cam/Crank Relearn Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Replace the Crank Position Sensor in accordance with the Service Information. With the scan tool, perform the Cam/Crank Relearn Procedure. The Cam/Crank Relearn Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
10. **CHECK THE CKP (K24) SIGNAL CIRCUIT FOR A SHORT TO GROUND**
    1. Turn the ignition off.

2. Disconnect the PCM C2 harness connector.
3. Check for continuity between ground and the CKP (K24) Signal circuit at the CKP Sensor harness connector.

   Is there continuity between ground and the CKP (K24) Signal circuit?

   Yes

   - Repair the CKP (K24) Signal circuit for a short to ground.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 11

11. **CHECK THE CKP (K24) SIGNAL CIRCUIT FOR A SHORT TO THE (K925) SENSOR GROUND**
    1. Check for continuity between the CKP (K24) Signal circuit and the (K925) Sensor Ground circuit at the CKP Sensor harness connector.

       Is there continuity between the CKP (K24) Signal circuit and the (K925) Sensor Ground circuit?

       Yes

       - Repair the short between the CKP (K24) Signal circuit and the (K925) Sensor Ground circuit.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 12
12. **CHECK THE CKP (K24) SIGNAL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. Measure the resistance of the CKP (K24) Signal circuit between the CKP Sensor harness connector and the PCM C2 harness connector.

       Is the resistance below 3.0 Ohms?

       Yes

       - Go To 13

       No

       - Repair the CKP (K24) Signal circuit for an open circuit or high resistance.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
13. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
       - Proper connector installation.

- Damaged connector locks.
- Corrosion.
- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0340-CAMSHAFT POSITION SENSOR CIRCUIT - BANK 1 SENSOR 1

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

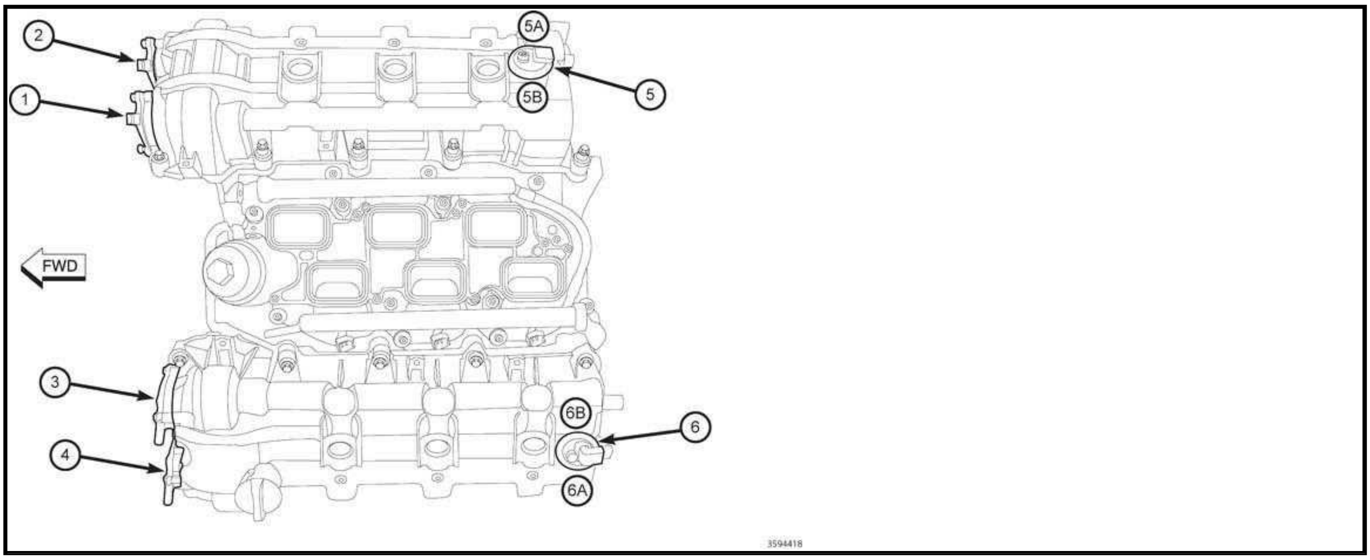
The Camshaft Position (CMP) Sensor circuits consist of a Powertrain Control Module (PCM) supplied 5-Volt reference circuit, low reference circuit, and an output signal circuit. The CMP Sensor detects magnetic flux from the peaks and valleys between the magnets of the tone wheel attached to the camshaft. As each magnet rotates past the CMP Sensor, the resulting change in the magnetic field is used by the sensor electronics to produce a digital output pulse. The sensor returns a digital ON/OFF DC voltage pulse of varying frequency output pulses per Camshaft revolution that represent an image of the camshaft tone wheel. The frequency of the CMP Sensor output depends on the velocity of the camshaft. The PCM decodes the tooth pattern to identify camshaft position. This information is then used to sequence the ignition timing and fuel injection events for the engine. The PCM also uses CMP Sensor output information to determine the camshaft relative position to the Crankshaft, to control the CMP Actuator operation if equipped.

NOTE: **The engine may still start even if either the Crankshaft Position (CKP) Sensor or CMP fails. The PCM eventually sorts out engine position and starts the vehicle on just one of these two inputs. However, there is a slight delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and tables below indicating the CMP Sensor, Position Solenoid/Phaser and DTC orientation).

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	CALLOUT #	RELATED CAM SENSOR DTCS	PHASER/ACTUATOR DTCS	MISALIGNMENT DTCS	COLD START PERFORMANCE DTCS
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

3.2L / 3.6L VVT Component Locations			
CALLOUT	DESCRIPTION	CALLOUT	DESCRIPTION
1	CMP Position Solenoid - Bank 1 Position 1 (INTAKE)	5A	CMP Sensor - Bank 1 Sensor 1 (EXHAUST)
2	CMP Position Solenoid - Bank 1 Position 2 (EXHAUST)	5B	CMP Sensor - Bank 1 Sensor 2 (INTAKE)
3	CMP Position Solenoid - Bank 2 Position 1 (INTAKE)	6	Bank 2 Camshaft Sensor
4	CMP Position Solenoid - Bank 2 Position 2 (EXHAUST)	6A	CMP Sensor - Bank 2 Sensor 1 (EXHAUST)
5	Bank 1 Camshaft Sensor	6B	CMP Sensor - Bank 2 Sensor 2 (INTAKE)



WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- Battery voltage is above approximately 11.0 volts.
- With the engine cranking and with the engine running.

SET CONDITION

- During cranking, at least 2.5 seconds have elapsed with a Crankshaft Position Sensor signal present but no Camshaft Position Sensor signal.
- With the engine running, the Camshaft Position Sensor signal is lost for at least 0.4 seconds with a Crankshaft Position Sensor signal present.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
LOW ENGINE OIL LEVEL
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT OPEN
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
5-VOLT SUPPLY CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 1/1 SIGNAL CIRCUIT SHORTED TO VOLTAGE
CMP 1/1 SIGNAL CIRCUIT SHORTED TO GROUND
CMP 1/1 SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 1/1 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CAMSHAFT POSITION SENSOR 1
TONE WHEEL LOOSE OR DAMAGED
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK THE ENGINE OIL LEVEL AND CONDITION**
    1. Turn the ignition off.

NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

- **LOW ENGINE OIL LEVEL**
- **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL**
- **INCORRECT ENGINE OIL VISCOSITY**
- **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

Were any of the above conditions present?

Yes

- Repair as necessary. If the engine oil was not at the proper level, top off the engine oil to the proper specification. Start the engine and allow it to idle for 2 - 3 minutes. Turn the engine off, ignition on, and using the scan tool, erase the DTC. Start the engine and drive the vehicle to verify repair. If the DTC does not return, repair is complete.
- If the DTC returns, Go To 3

No

- Go To 2

2. **CHECK FOR AN ACTIVE DTC**
   1. Turn the ignition on.
   2. With the scan tool, read DTCs and record on the repair order. Copy DTC and Freeze Frame information.
   3. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.

      WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

   4. With the scan tool, read DTCs.

      Is the DTC active or pending?

      Yes

      - Go To 3

      No

      - Go To 27
3. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are there any 5-Volt Reference, Dual Stage Oil Pump or Oil Pressure related DTCs active or pending?

      Yes

      - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

      No

      - Go To 4
4. **CHECK FOR RELATED CAM SENSOR DTCS**

   Is the P0365 or P0369 DTC also active at this time?

   Yes

   - Go To 5

   No

- Go To 8

5. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT VOLTAGE**

   NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

   1. Turn the ignition off.
   2. Disconnect the CMP Sensor 1 harness connector.
   3. Turn the ignition on.
   4. Measure the voltage on the (F856) 5-Volt Supply circuit at the CMP Sensor 1 harness connector.

      Is the voltage between 4.8 and 5.2 volts?

      Yes

      - Go To 6

      No

      - Repair the (F856) 5-Volt Supply circuit for an open or shorted circuit.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE CMP SENSOR 1 (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.

      CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   3. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
   4. Measure the resistance of the CMP Sensor 1 (K900) Sensor Ground circuit between the CMP Sensor 1 harness connector and the GPEC Adaptor.

      Is the resistance below 3.0 Ohms?

      Yes

      - Go To 7

      No

      - Repair the CMP Sensor 1 (K900) Sensor Ground circuit for an open or high resistance.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
   1. Remove and exchange the CMP Sensor 1 with the CMP Sensor on the opposite bank.

      NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed**

every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.

2. Reconnect the PCM C2 and CMP Sensor harness connectors.
3. Turn the ignition on,
4. With the scan tool, erase DTCs.
5. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.
6. With the scan tool, read DTCs.

   Did the CMP Sensor DTCs for the opposite bank set?

   Yes

   - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 22

8. **CHECK THE CMP SENSOR 1 (K44) POSITION SIGNAL 1 CIRCUIT FOR A SHORT TO VOLTAGE**

   NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

   1. Disconnect the CMP Sensor 1 harness connector.
   2. Measure the voltage on the CMP Sensor 1 (K44) Position Signal 1 circuit in the CMP Sensor 1 harness connector.

      Is the voltage above 5.2 volts?

      Yes

      - Repair the CMP Sensor 1 (K44) Position Signal 1 circuit for a short to voltage.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 9

9. **CHECK THE CMP SENSOR 1 (K44) POSITION SIGNAL 1 CIRCUIT FOR A SHORT TO GROUND**
   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.
   3. Check for continuity between ground and the CMP Sensor 1 (K44) Position Signal 1 circuit at the CMP Sensor 1 harness connector.

Is there continuity between ground and the CMP Sensor 1 (K44) Position Signal 1 circuit?

Yes

- Repair the CMP Sensor 1 (K44) Position Signal 1 circuit for a short to ground.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 10

10. **CHECK FOR THE CMP SENSOR 1 (K44) POSITION SIGNAL 1 CIRCUIT SHORTED TO THE CMP SENSOR 1 (K900) SENSOR GROUND CIRCUIT**
    1. Check for continuity between the CMP Sensor 1 (K44) Position Signal 1 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit at the CMP Sensor 1 harness connector.

       Is there continuity between ground and the CMP Sensor 1 (K44) Position Signal 1 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit?

       Yes

       - Repair the short between the CMP Sensor 1 (K44) Position Signal 1 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 11

11. **CHECK THE CMP SENSOR 1 (K44) POSITION SIGNAL 1 CIRCUIT FOR AN OPEN/HIGH RESISTANCE**

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
    2. Measure the resistance of the CMP Sensor 1 (K44) Position Signal 1 circuit between the CMP Sensor 1 harness connector and the GPEC Adaptor.

       Is the resistance below 3.0 Ohms?

       Yes

       - Go To 12

       No

       - Repair the CMP Sensor 1 (K44) Position Signal 1 circuit for an open or high resistance.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

12. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure**

with the adaptor tool and a gauge on the later model engines where the adaptor can be used.

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

Is the oil pressure reading stable and above 16.0 psi?

Yes

- Go To 13

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 14

No

- Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK THE CAMSHAFT 1/2 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.
    2. Remove the VVT Exhaust Solenoid 1/2.
    3. Inspect the spring loaded spool valve on the Oil Control Valve.

       NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

    4. Push and release the spring loaded spool valve against the return spring with a small punch.

       NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

    Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

    Yes

    - Go To 15

    No

    - Replace the Camshaft 1/2 Oil Control Valve in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

15. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
    1. Remove and exchange the CMP Sensor 1 with the CMP Sensor on the opposite bank.

       NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

    2. Reconnect the PCM C2 and Cam Sensor harness connectors.
    3. Turn the ignition on,
    4. With the scan tool, erase DTCs.
    5. Start the engine and allow it to idle or crank the engine if it will not start.
    6. With the scan tool, read DTCs.

    Did the CMP Sensor DTCs for the opposite bank set as active?

    Yes

    - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank**

Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

    - Go To 16

16. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    2. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Were any issues found with the CMP Sensor Tone Wheel?

    Yes

    - Replace the Camshaft Assembly in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 17

17. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain and tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 18

18. **CHECK THE CAM PHASER AND CAMSHAFT ASSEMBLY**
    1. Check the Cam Phaser to verify it has returned to lock pin.

2. Put a wrench on the flat of the Camshaft behind the phaser and attempt to move the Camshaft back and forth.

   NOTE: **The Cam Phaser should always return to lock pin when the engine is turned off. If the Cam Phaser is not at lock pin, there will be movement felt between the Camshaft and the Cam Phaser.**

   Is there movement between the Camshaft and Cam Phaser?

   Yes

   - Replace the Cam Phaser in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Go To 19

   No

   - Replace the Cam Phaser and Camshaft in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Go To 19

19. **VERIFY THE REPAIR**
   1. With the scan tool, erase DTCs.
   2. Test drive the vehicle in accordance with the Freeze Frame data collected.

   Did the DTC return?

   Yes

   - Go To 20

   No

   - Repair is complete.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

20. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.

- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 21

No

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
- Test complete.

21. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

    Did the CMP Sensor DTC return?

    Yes

    - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair is complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

22. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

   NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

   Is the oil pressure reading stable and above 16.0 psi?

   Yes

   - Go To 23

   No

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

23. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

    NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

    Is the oil pressure reading stable and above 14.0 psi?

    Yes

    - Go To 24

    No

    - Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or

CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
 - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

24. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 25
25. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

        Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.

9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 26

    No

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
    - Test complete.

26. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

       Did the CMP Sensor DTC return?

       Yes

       - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Replacing the PCM repaired the fault.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

27. **WIRE HARNESS/CKP SENSOR INSPECTION**
    1. Turn the ignition off.
    2. Disconnect the harness connectors at the PCM and Cam Sensor. Inspect for wire chaffing or rub conditions, spread terminals, terminals pushed out of the wiring connector, bent terminals at the PCM and Cam Sensor, water in the connector cavities, presence of corrosion on the terminals of the connectors or components.
    3. Visually inspect the mounting area of Cam Sensor for debris/damage or a loose sensor. Remove the Cam Sensor and inspect the end of the sensor for signs of damage or debris. Rotate the engine and if possible, inspect the tone wheel for any signs of damage. Reinstall the Cam Sensor and ensure that the sensor is properly installed and torqued to proper specification.

NOTE:	**Due to the fact that this DTC is set by an intermittent loss of the signal, the DTC may be caused by a poor connection at the Cam Sensor or PCM terminals, or a poor signal between the Cam Sensor**

and tone wheel. Because of this, unplugging and reconnecting the harness connectors, or repositioning the Cam Sensor will often repair the condition that set the DTC.

Were any problems found?

Yes

- Perform the appropriate repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 28

28. **CHECK THE VEHICLE'S REPAIR HISTORY**
    1. Check the history of the vehicle for previous Cam Sensor related DTCs.

    Did the repair history show that the vehicle was previously in the dealership with a Cam Sensor fault?

    Yes

    - If the current DTC being diagnosed is for the **same** engine bank as the DTC that set on the previous visit, perform the diagnostics starting at test step #12 in this diagnostic procedure.
    - If the current DTC being diagnosed is for the **opposite** engine bank as the DTC that set on the previous visit, replace the Cam Sensor in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Swap the Cam Sensor with the Cam Sensor on the opposite bank and clear DTCs. The cause may have been a poor connection at one of the harness connectors. Unplugging and reconnecting the harness connector may resolve the issue. Verify the DTC does not return.

    NOTE: **The sensors must be exchanged to aid in determining the possible failure if the vehicle returns to the dealership in the future with another Cam Sensor related DTC.**

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0344-CAMSHAFT POSITION SENSOR INTERMITTENT - BANK 1 SENSOR 1

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Camshaft Position (CMP) Sensor circuits consist of a Powertrain Control Module (PCM) supplied 5-Volt reference circuit, low reference circuit, and an output signal circuit. The CMP Sensor detects magnetic flux from the peaks and valleys between the magnets of the tone wheel attached to the camshaft. As each magnet rotates past the CMP Sensor, the resulting change in the magnetic field is used by the sensor electronics to produce a digital output pulse. The sensor returns a digital ON/OFF DC voltage pulse of varying frequency output pulses per Camshaft revolution that represent an image of the camshaft tone wheel. The frequency of the CMP Sensor output depends on the velocity of the camshaft. The PCM decodes the tooth pattern to identify camshaft position. This information is then used to sequence the ignition timing and fuel injection events for the engine. The PCM also uses CMP Sensor output information to determine the camshaft relative position to the Crankshaft, to control the CMP Actuator operation if equipped.

NOTE: **The engine may still start even if either the Crankshaft Position (CKP) Sensor or CMP fails. The PCM eventually sorts out engine position and starts the vehicle on just one of these two inputs. However, there is a slight delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and tables below indicating the CMP Sensor, Position Solenoid/Phaser and DTC orientation).

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	**CALLOUT #**	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERFORMANCE DTCS**
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

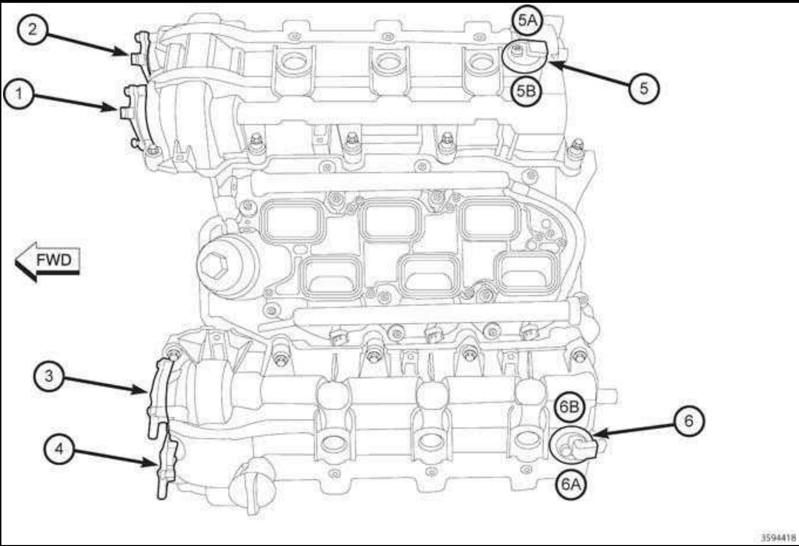
CALLOUT	**DESCRIPTION**	**CALLOUT**	**DESCRIPTION**
1	CMP Position Solenoid - Bank 1 Position 1 (INTAKE)	5A	CMP Sensor - Bank 1 Sensor 1 (EXHAUST)
2	CMP Position Solenoid - Bank 1 Position 2 (EXHAUST)	5B	CMP Sensor - Bank 1 Sensor 2 (INTAKE)
3	CMP Position Solenoid - Bank 2 Position 1 (INTAKE)	6	Bank 2 Camshaft Sensor
4	CMP Position Solenoid - Bank 2 Position 2 (EXHAUST)	6A	CMP Sensor - Bank 2 Sensor 1 (EXHAUST)
5	Bank 1 Camshaft Sensor	6B	CMP Sensor - Bank 2 Sensor 2 (INTAKE)



WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage is above approximately 11.0 volts.

SET CONDITION

- With the engine running, the Powertrain Control Module (PCM) acquires and locks in on a pattern for the Camshaft Position (CMP) Sensor signal. If the CMP Sensor signal pattern changes between unlock and lock at least four times during a period of eight Crankshaft revolutions, a fault is set.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
LOW ENGINE OIL LEVEL
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT OPEN
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
5-VOLT SUPPLY CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 1/1 SIGNAL CIRCUIT SHORTED TO VOLTAGE
CMP 1/1 SIGNAL CIRCUIT SHORTED TO GROUND
CMP 1/1 SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 1/1 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CAMSHAFT POSITION SENSOR 1
CAMSHAFT TONE WHEEL LOOSE/DAMAGED OR MISALIGNED
CAMSHAFT 1/2 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT 1/2 PHASER FAULTY OR INTERMITTENTLY BINDING/STICKING
POWERTRAIN CONTROL MODULE (PCM)

Possible Causes
OIL PRESSURE ISSUE IN CYLINDER HEAD

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK THE ENGINE OIL LEVEL AND CONDITION**
    1. Turn the ignition off.

    NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

    - **LOW ENGINE OIL LEVEL**
    - **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL**
    - **INCORRECT ENGINE OIL VISCOSITY**
    - **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
    - **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

    Were any of the above conditions present?

    Yes

    - Repair as necessary. If the engine oil was not at the proper level, top off the engine oil to the proper specification. Start the engine and allow it to idle for 2 - 3 minutes. Turn the engine off, ignition on, and using the scan tool, erase the DTC. Start the engine and drive the vehicle to verify repair. If the DTC does not return, repair is complete.
    - If the DTC returns, Go To 3

    No

    - Go To 2
2. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on the repair order. Copy DTC and Freeze Frame information.
    3. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    4. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 3

No

- Go To 27

3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

        Are there any 5-Volt Reference, Dual Stage Oil Pump or Oil Pressure related DTCs active or pending?

        Yes

        - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

        No

        - Go To 4

4. **CHECK FOR RELATED CAM SENSOR DTCS**

    Is the P0365 or P0369 DTC also active at this time?

    Yes

    - Go To 5

    No

    - Go To 8

5. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT VOLTAGE**

    NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

    1. Turn the ignition off.
    2. Disconnect the CMP Sensor 1 harness connector.
    3. Turn the ignition on.
    4. Measure the voltage on the (F856) 5-Volt Supply circuit at the CMP Sensor 1 harness connector.

        Is the voltage between 4.8 and 5.2 volts?

        Yes

        - Go To 6

        No

        - Repair the (F856) 5-Volt Supply circuit for an open or shorted circuit.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE CMP SENSOR 1 (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. Turn the ignition off.
    2. Disconnect the PCM C2 harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

3. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
4. Measure the resistance of the (K900) Sensor Ground circuit between the CMP Sensor 1 harness connector and the GPEC Adaptor.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 7

   No

   - Repair the (K900) Sensor Ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
   1. Remove and exchange the CMP Sensor 1 with the CMP Sensor on the opposite bank.

      NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

   2. Reconnect the PCM C2 and CMP Sensor harness connectors.
   3. Turn the ignition on,
   4. With the scan tool, erase DTCs.
   5. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.
   6. With the scan tool, read DTCs.

   Did the CMP Sensor DTCs for the opposite bank set?

   Yes

   - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 22

8. **CHECK THE CMP SENSOR 1 (K44) POSITION SIGNAL 1 CIRCUIT FOR A SHORT TO VOLTAGE**

   NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

   1. Disconnect the CMP Sensor 1 harness connector.
   2. Measure the voltage on the CMP Sensor 1 (K44) Position Signal 1 circuit in the CMP Sensor 1 harness connector.

      Is the voltage above 5.2 volts?

      Yes

      - Repair the CMP Sensor 1 (K44) Position Signal 1 circuit for a short to voltage.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 9
9. **CHECK THE CMP SENSOR 1 (K44) POSITION SIGNAL 1 CIRCUIT FOR A SHORT TO GROUND**
   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.
   3. Check for continuity between ground and the CMP Sensor 1 (K44) Position Signal 1 circuit at the CMP Sensor 1 harness connector.

      Is there continuity between ground and the CMP Sensor 1 (K44) Position Signal 1 circuit?

      Yes

      - Repair the CMP Sensor 1 (K44) Position Signal 1 circuit for a short to ground.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 10
10. **CHECK FOR THE CMP SENSOR 1 (K44) POSITION SIGNAL 1 CIRCUIT SHORTED TO THE CMP SENSOR 1 (K900) SENSOR GROUND CIRCUIT**
    1. Check for continuity between the CMP Sensor 1 (K44) Position Signal 1 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit at the CMP Sensor 1 harness connector.

       Is there continuity between ground and the CMP Sensor 1 (K44) Position Signal 1 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit?

       Yes

       - Repair the short between the CMP Sensor 1 (K44) Position Signal 1 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

- Go To 11

11. **CHECK THE CMP SENSOR 1 (K44) POSITION SIGNAL 1 CIRCUIT FOR AN OPEN/HIGH RESISTANCE**

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
    2. Measure the resistance of the CMP Sensor 1 (K44) Position Signal 1 circuit between the CMP Sensor 1 harness connector and the GPEC Adaptor.

       Is the resistance below 3.0 Ohms?

       Yes

       - Go To 12

       No

       - Repair the CMP Sensor 1 (K44) Position Signal 1 circuit for an open or high resistance.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

12. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

    1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
    2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
    3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
    4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
    5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

       NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

       Is the oil pressure reading stable and above 16.0 psi?

       Yes

       - Go To 13

       No

       - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

    NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

    Is the oil pressure reading stable and above 14.0 psi?

    Yes

    - Go To 14

    No

    - Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK THE CAMSHAFT 1/2 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.
    2. Remove the VVT Intake Solenoid 1/2.
    3. Inspect the spring loaded spool valve on the Oil Control Valve.

    NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

    4. Push and release the spring loaded spool valve against the return spring with a small punch.

    NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

    Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

    Yes

    - Go To 15

    No

    - Replace the Camshaft 1/2 Oil Control Valve in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing

chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

15. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
    1. Remove and exchange the CMP Sensor 1 with the CMP Sensor on the opposite bank.

       NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

    2. Reconnect the PCM C2 and Cam Sensor harness connectors.
    3. Turn the ignition on,
    4. With the scan tool, erase DTCs.
    5. Start the engine and allow it to idle or crank the engine if it will not start.
    6. With the scan tool, read DTCs.

    Did the CMP Sensor DTCs for the opposite bank set as active?

    Yes

    - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 16

16. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    2. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Were any issues found with the CMP Sensor Tone Wheel?

    Yes

    - Replace the Camshaft Assembly in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 17

17. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 18

18. **CHECK THE CAM PHASER AND CAMSHAFT ASSEMBLY**
    1. Check the Cam Phaser to verify it has returned to lock pin.
    2. Put a wrench on the flat of the Camshaft behind the phaser and attempt to move the Camshaft back and forth.

    NOTE: **The Cam Phaser should always return to lock pin when the engine is turned off. If the Cam Phaser is not at lock pin, there will be movement felt between the Camshaft and the Cam Phaser.**

    Is there movement between the Camshaft and Cam Phaser?

    Yes

    - Replace the Cam Phaser in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Go To 19

    No

    - Replace the Cam Phaser and Camshaft in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Go To 19

19. **VERIFY THE REPAIR**
    1. With the scan tool, erase DTCs.

2. Test drive the vehicle in accordance with the Freeze Frame data collected.

   Did the DTC return?

   Yes

   - Go To 20

   No

   - Repair is complete.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

20. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
       - Proper connector installation.
       - Damaged connector locks.
       - Corrosion.
       - Other signs of water intrusion.
       - Weather seal damage (if equipped).
       - Bent terminals.
       - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
       - Terminals that have been pushed back into the connector cavity.
       - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Go To 21

        No

        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

- Test complete.

21. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

    Did the CMP Sensor DTC return?

    Yes

    - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair is complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

22. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.

    1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
    2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
    3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
    4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
    5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

       NOTE: If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.

    Is the oil pressure reading stable and above 16.0 psi?

    Yes

    - Go To 23

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

23. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

    NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

    Is the oil pressure reading stable and above 14.0 psi?

    Yes

    - Go To 24

    No

    - Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

24. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 25

25. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Go To 26

        No

        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
        - Test complete.
26. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

       Did the CMP Sensor DTC return?

Yes

- Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Repair is complete.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

27. **WIRE HARNESS/CKP SENSOR INSPECTION**
    1. Turn the ignition off.
    2. Disconnect the harness connectors at the PCM and Cam Sensor. Inspect for wire chaffing or rub conditions, spread terminals, terminals pushed out of the wiring connector, bent terminals at the PCM and Cam Sensor, water in the connector cavities, presence of corrosion on the terminals of the connectors or components.
    3. Visually inspect the mounting area of Cam Sensor for debris/damage or a loose sensor. Remove the Cam Sensor and inspect the end of the sensor for signs of damage or debris. Rotate the engine and if possible, inspect the tone wheel for any signs of damage. Reinstall the Cam Sensor and ensure that the sensor is properly installed and torqued to proper specification.

    NOTE: **Due to the fact that this DTC is set by an intermittent loss of the signal, the DTC may be caused by a poor connection at the Cam Sensor or PCM terminals, or a poor signal between the Cam Sensor and tone wheel. Because of this, unplugging and reconnecting the harness connectors, or repositioning the Cam Sensor will often repair the condition that set the DTC.**

    Were any problems found?

    Yes

    - Perform the appropriate repair.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 28
28. **CHECK THE VEHICLE'S REPAIR HISTORY**
    1. Check the history of the vehicle for previous Cam Sensor related DTCs.

    Did the repair history show that the vehicle was previously in the dealership with a Cam Sensor fault?

    Yes

    - If the current DTC being diagnosed is for the **same** engine bank as the DTC that set on the previous visit, perform the diagnostics starting at test step #12 in this diagnostic procedure.
    - If the current DTC being diagnosed is for the **opposite** engine bank as the DTC that set on the previous visit, replace the Cam Sensor in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing

chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Swap the Cam Sensor with the Cam Sensor on the opposite bank and clear DTCs. The cause may have been a poor connection at one of the harness connectors. Unplugging and reconnecting the harness connector may resolve the issue. Verify the DTC does not return.

NOTE: **The sensors must be exchanged to aid in determining the possible failure if the vehicle returns to the dealership in the future with another Cam Sensor related DTC.**

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0345-CAMSHAFT POSITION SENSOR CIRCUIT - BANK 2 SENSOR 1

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Camshaft Position (CMP) Sensor circuits consist of a Powertrain Control Module (PCM) supplied 5-Volt reference circuit, low reference circuit, and an output signal circuit. The CMP Sensor detects magnetic flux from the peaks and valleys between the magnets of the tone wheel attached to the camshaft. As each magnet rotates past the CMP Sensor, the resulting change in the magnetic field is used by the sensor electronics to produce a digital output pulse. The sensor returns a digital ON/OFF DC voltage pulse of varying frequency output pulses per Camshaft revolution that represent an image of the camshaft tone wheel. The frequency of the CMP Sensor output depends on the velocity of the camshaft. The PCM decodes the tooth pattern to identify camshaft position. This information is then used to sequence the ignition timing and fuel injection events for the engine. The PCM also uses CMP Sensor output information to determine the camshaft relative position to the Crankshaft, to control the CMP Actuator operation if equipped.

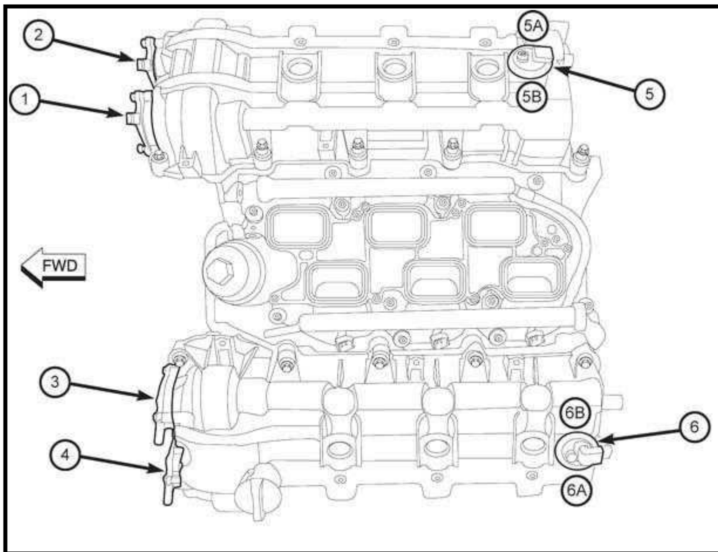
NOTE: **The engine may still start even if either the Crankshaft Position (CKP) Sensor or CMP fails. The PCM eventually sorts out engine position and starts the vehicle on just one of these two inputs. However, there is a slight delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and tables below indicating the CMP Sensor, Position Solenoid/Phaser and DTC orientation).

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	CALLOUT #	RELATED CAM SENSOR DTCS	PHASER/ACTUATOR DTCS	MISALIGNMENT DTCS	COLD START PERFORMANCE DTCS
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	**CALLOUT #**	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERFORMANCE DTCS**
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

3.2L / 3.6L VVT Component Locations			
CALLOUT	**DESCRIPTION**	**CALLOUT**	**DESCRIPTION**
1	CMP Position Solenoid - Bank 1 Position 1 (INTAKE)	5A	CMP Sensor - Bank 1 Sensor 1 (EXHAUST)
2	CMP Position Solenoid - Bank 1 Position 2 (EXHAUST)	5B	CMP Sensor - Bank 1 Sensor 2 (INTAKE)
3	CMP Position Solenoid - Bank 2 Position 1 (INTAKE)	6	Bank 2 Camshaft Sensor
4	CMP Position Solenoid - Bank 2 Position 2 (EXHAUST)	6A	CMP Sensor - Bank 2 Sensor 1 (EXHAUST)
5	Bank 1 Camshaft Sensor	6B	CMP Sensor - Bank 2 Sensor 2 (INTAKE)



WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine cranking and with the engine running.
- Battery voltage is above approximately 11.0 volts.

SET CONDITION

- During cranking, at least 2.5 seconds have elapsed with a Crankshaft Position Sensor signal present but no Camshaft Position Sensor signal.
- With the engine running, the Camshaft Position Sensor signal is lost for at least 0.4 seconds with a Crankshaft Position Sensor signal present.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
LOW ENGINE OIL LEVEL
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT OPEN
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
5-VOLT SUPPLY CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 2/1 SIGNAL CIRCUIT SHORTED TO VOLTAGE
CMP 2/1 SIGNAL CIRCUIT SHORTED TO GROUND
CMP 2/1 SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 2/1 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CAMSHAFT POSITION SENSOR 2
CAMSHAFT TONE WHEEL LOOSE/DAMAGED OR MISALIGNED
CAMSHAFT 2/2 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT 2/2 PHASER FAULTY OR INTERMITTENTLY BINDING/STICKING
POWERTRAIN CONTROL MODULE (PCM)
OIL PRESSURE ISSUE IN CYLINDER HEAD

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK THE ENGINE OIL LEVEL AND CONDITION**
    1. Turn the ignition off.

    NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

    - **LOW ENGINE OIL LEVEL**
    - **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL**
    - **INCORRECT ENGINE OIL VISCOSITY**
    - **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
    - **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

    Were any of the above conditions present?

    Yes

    - Repair as necessary. If the engine oil was not at the proper level, top off the engine oil to the proper specification. Start the engine and allow it to idle for 2 - 3 minutes. Turn the engine off, ignition on, and using the scan tool, erase the DTC. Start the engine and drive the vehicle to verify repair. If the DTC does not return, repair is complete.

- If the DTC returns, Go To 3

No

- Go To 2

2. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on the repair order. Copy DTC and Freeze Frame information.
    3. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    4. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 3

    No

    - Go To 27
3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

    Are there any 5-Volt Reference, Dual Stage Oil Pump or Oil Pressure related DTCs active or pending?

    Yes

    - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

    No

    - Go To 4
4. **CHECK FOR RELATED CAM SENSOR DTCS**

    Is the P0390 or P0394 DTC also active at this time?

    Yes

    - Go To 5

    No

    - Go To 8
5. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT**

NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

1. Turn the ignition off.
2. Disconnect the CMP Sensor 2 harness connector.
3. Turn the ignition on.
4. Measure the voltage on the (F856) 5-Volt Supply circuit at the CMP Sensor 2 harness connector.

   Is the voltage between 4.8 and 5.2 volts?

   Yes

   - Go To 6

   No

   - Repair the (F856) 5-Volt Supply circuit for an open or shorted circuit.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE CMP SENSOR 2 (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.

      CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   3. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
   4. Measure the resistance of the CMP Sensor 2 (K900) Sensor Ground circuit between the CMP Sensor 2 harness connector and the GPEC Adaptor.

      Is the resistance below 3.0 Ohms?

      Yes

      - Go To 7

      No

      - Repair the CMP Sensor 2 (K900) Sensor Ground circuit for an open or high resistance.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
   1. Remove and exchange the CMP Sensor 2 with the CMP Sensor on the opposite bank.

      NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or**

gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.

2. Reconnect the PCM C2 and CMP Sensor harness connectors.
3. Turn the ignition on,
4. With the scan tool, erase DTCs.
5. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.
6. With the scan tool, read DTCs.

Did the CMP Sensor DTCs for the opposite bank set?

Yes

- Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 22

8. **CHECK THE CMP SENSOR 2 (K444) SIGNAL 1 CIRCUIT FOR A SHORT TO VOLTAGE**

NOTE: Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.

1. Disconnect the CMP Sensor 2 harness connector.
2. Measure the voltage on the CMP Sensor 2 (K444) Signal 1 circuit in the CMP Sensor 2 harness connector.

Is the voltage above 5.2 volts?

Yes

- Repair the CMP Sensor 2 (K444) Signal 1 circuit for a short to voltage.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 9

9. **CHECK THE CMP SENSOR 2 (K444) SIGNAL 1 CIRCUIT FOR A SHORT TO GROUND**

1. Turn the ignition off.
2. Disconnect the PCM C2 harness connector.
3. Check for continuity between ground and the CMP Sensor 2 (K444) Signal 1 circuit at the CMP Sensor 2 harness connector.

Is there continuity between ground and the CMP Sensor 2 (K444) Signal 1 circuit?

Yes

- Repair the CMP Sensor 2 (K444) Signal 1 circuit for a short to ground.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 10

10. **CHECK FOR THE CMP SENSOR 2 (K444) SIGNAL 1 CIRCUIT SHORTED TO THE CMP SENSOR 2 (K900) SENSOR GROUND CIRCUIT**
    1. Check for continuity between the CMP Sensor 2 (K444) Signal 1 circuit and the CMP Sensor 2 (K900) Sensor Ground circuit at the CMP Sensor 2 harness connector.

    Is there continuity between ground and the CMP Sensor 2 (K444) Signal 1 circuit and the CMP Sensor 2 (K900) Sensor Ground circuit?

    Yes

    - Repair the short between the CMP Sensor 2 (K444) Signal 1 circuit and the CMP Sensor 2 (K900) Sensor Ground circuit.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 11

11. **CHECK THE CMP SENSOR 2 (K444) SIGNAL 1 CIRCUIT FOR AN OPEN/HIGH RESISTANCE**

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
    2. Measure the resistance of the CMP Sensor 2 (K444) Signal 1 circuit between the CMP Sensor 2 harness connector and the GPEC Adaptor.

    Is the resistance below 3.0 Ohms?

    Yes

    - Go To 12

    No

    - Repair the CMP Sensor 2 (K444) Signal 1 circuit for an open or high resistance.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

12. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

Is the oil pressure reading stable and above 16.0 psi?

Yes

- Go To 13

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

NOTE: **The oil pressure reading at the Cylinder Head should be within above 14.0 psi.**

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 14

No

- Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK THE CAMSHAFT 2/2 OIL CONTROL VALVE OPERATION**

1. Turn the ignition off.
2. Remove the Camshaft Position Solenoid 2/2.
3. Inspect the spring loaded spool valve on the Oil Control Valve.

   NOTE: The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.

4. Push and release the spring loaded spool valve against the return spring with a small punch.

   NOTE: The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.

   Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

   Yes

   - Go To 15

   No

   - Replace the Camshaft 2/2 Oil Control Valve in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

15. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
    1. Remove and exchange the CMP Sensor 2 with the CMP Sensor on the opposite bank.

       NOTE: Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.

    2. Reconnect the PCM C2 and Cam Sensor harness connectors.
    3. Turn the ignition on,
    4. With the scan tool, erase DTCs.
    5. Start the engine and allow it to idle or crank the engine if it will not start.
    6. With the scan tool, read DTCs.

    Did the CMP Sensor DTCs for the opposite bank set as active?

    Yes

    - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears.

Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 16

16. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    2. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Were any issues found with the CMP Sensor Tone Wheel?

    Yes

    - Replace the Camshaft Assembly in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 17

17. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 18

18. **CHECK THE CAM PHASER AND CAMSHAFT ASSEMBLY**
    1. Check the Cam Phaser to verify it has returned to lock pin.

2. Put a wrench on the flat of the Camshaft behind the phaser and attempt to move the Camshaft back and forth.

   NOTE: **The Cam Phaser should always return to lock pin when the engine is turned off. If the Cam Phaser is not at lock pin, there will be movement felt between the Camshaft and the Cam Phaser.**

   Is there movement between the Camshaft and Cam Phaser?

   Yes

   - Replace the Cam Phaser in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Go To 19

   No

   - Replace the Cam Phaser and Camshaft in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Go To 19

19. **VERIFY THE REPAIR**
   1. With the scan tool, erase DTCs.
   2. Test drive the vehicle in accordance with the Freeze Frame data collected.

   Did the DTC return?

   Yes

   - Go To 20

   No

   - Repair is complete.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

20. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.

- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 21

No

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
- Test complete.

21. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

    Did the CMP Sensor DTC return?

    Yes

    - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair is complete.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

22. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.

    1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
    2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
    3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
    4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
    5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

       NOTE: If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.

    Is the oil pressure reading stable and above 16.0 psi?

    Yes

    - Go To 23

    No

    - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

23. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

       NOTE: The oil pressure reading at the Cylinder Head should be above 14.0 psi.

    Is the oil pressure reading stable and above 14.0 psi?

    Yes

    - Go To 24

    No

    - Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

24. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 25
25. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

    Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.

7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 26

    No

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
    - Test complete.

26. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

       Did the CMP Sensor DTC return?

       Yes

       - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Repair is complete.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

27. **WIRE HARNESS/CKP SENSOR INSPECTION**
    1. Turn the ignition off.
    2. Disconnect the harness connectors at the PCM and Cam Sensor. Inspect for wire chaffing or rub conditions, spread terminals, terminals pushed out of the wiring connector, bent terminals at the PCM and Cam Sensor, water in the connector cavities, presence of corrosion on the terminals of the connectors or components.
    3. Visually inspect the mounting area of Cam Sensor for debris/damage or a loose sensor. Remove the Cam Sensor and inspect the end of the sensor for signs of damage or debris. Rotate the engine and

if possible, inspect the tone wheel for any signs of damage. Reinstall the Cam Sensor and ensure that the sensor is properly installed and torqued to proper specification.

NOTE: **Due to the fact that this DTC is set by an intermittent loss of the signal, the DTC may be caused by a poor connection at the Cam Sensor or PCM terminals, or a poor signal between the Cam Sensor and tone wheel. Because of this, unplugging and reconnecting the harness connectors, or repositioning the Cam Sensor will often repair the condition that set the DTC.**

Were any problems found?

Yes

- Perform the appropriate repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 28

28. **CHECK THE VEHICLE'S REPAIR HISTORY**
    1. Check the history of the vehicle for previous Cam Sensor related DTCs.

    Did the repair history show that the vehicle was previously in the dealership with a Cam Sensor fault?

    Yes

    - If the current DTC being diagnosed is for the **same** engine bank as the DTC that set on the previous visit, perform the diagnostics starting at test step #12 in this diagnostic procedure.
    - If the current DTC being diagnosed is for the **opposite** engine bank as the DTC that set on the previous visit, replace the Cam Sensor in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Swap the Cam Sensor with the Cam Sensor on the opposite bank and clear DTCs. The cause may have been a poor connection at one of the harness connectors. Unplugging and reconnecting the harness connector may resolve the issue. Verify the DTC does not return.

      NOTE: **The sensors must be exchanged to aid in determining the possible failure if the vehicle returns to the dealership in the future with another Cam Sensor related DTC.**

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0349-CAMSHAFT POSITION SENSOR INTERMITTENT - BANK 2 SENSOR 1

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Camshaft Position (CMP) Sensor circuits consist of a Powertrain Control Module (PCM) supplied 5-Volt reference circuit, low reference circuit, and an output signal circuit. The CMP Sensor detects magnetic flux from the peaks and valleys between the magnets of the tone wheel attached to the camshaft. As each magnet rotates past the CMP Sensor, the resulting change in the magnetic field is used by the sensor electronics to produce a digital output pulse. The sensor returns a digital ON/OFF DC voltage pulse of varying frequency output pulses per Camshaft revolution that represent an image of the camshaft tone wheel. The frequency of the CMP Sensor output depends on the velocity of the camshaft. The PCM decodes the tooth pattern to identify camshaft position. This information is then used to sequence the ignition timing and fuel injection events for the engine. The PCM also uses CMP Sensor output information to determine the camshaft relative position to the Crankshaft, to control the CMP Actuator operation if equipped.

NOTE: **The engine may still start even if either the Crankshaft Position (CKP) Sensor or CMP fails. The PCM eventually sorts out engine position and starts the vehicle on just one of these two inputs. However, there is a slight delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and tables below indicating the CMP Sensor, Position Solenoid/Phaser and DTC orientation).

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	CALLOUT #	RELATED CAM SENSOR DTCS	PHASER/ACTUATOR DTCS	MISALIGNMENT DTCS	COLD START PERFORMANCE DTCS
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

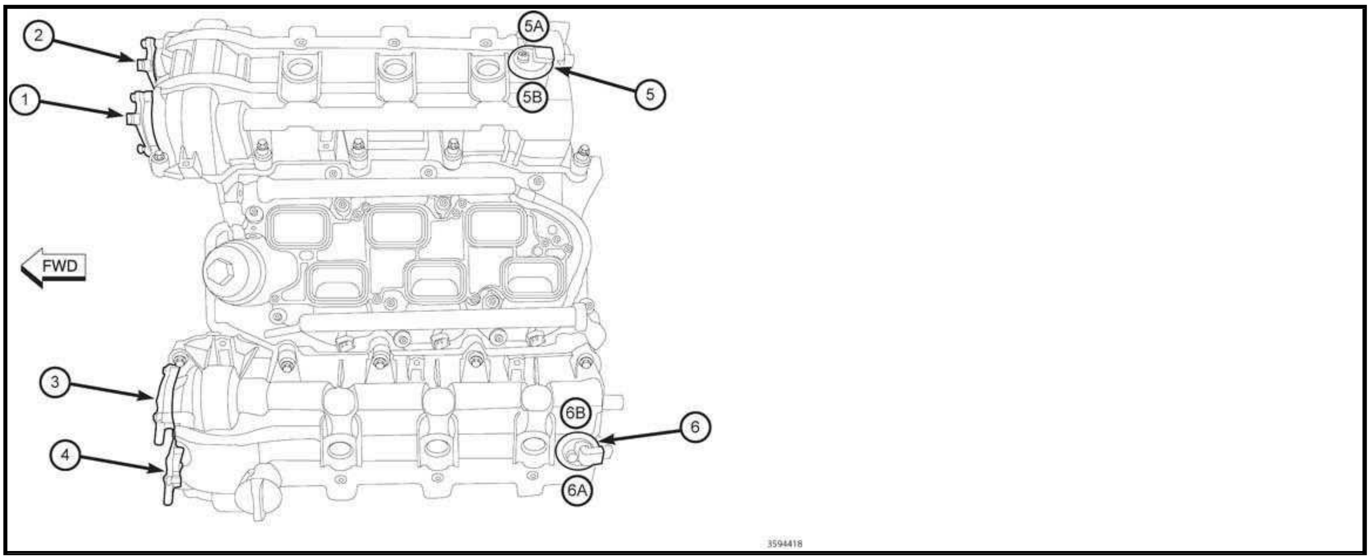
2	CMP Position Solenoid - Bank 1 Position 2 (EXHAUST)	5B	CMP Sensor - Bank 1 Sensor 2 (INTAKE)
3	CMP Position Solenoid - Bank 2 Position 1 (INTAKE)	6	Bank 2 Camshaft Sensor
4	CMP Position Solenoid - Bank 2 Position 2 (EXHAUST)	6A	CMP Sensor - Bank 2 Sensor 1 (EXHAUST)
5	Bank 1 Camshaft Sensor	6B	CMP Sensor - Bank 2 Sensor 2 (INTAKE)



WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage is above approximately 11.0 volts.

SET CONDITION

- With the engine running, the Powertrain Control Module (PCM) acquires and locks in on a pattern for the Camshaft Position (CMP) Sensor signal. If the CMP Sensor signal pattern changes between unlock and lock at least four times during a period of eight Crankshaft revolutions, a fault is set.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
LOW ENGINE OIL LEVEL
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT OPEN
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
5-VOLT SUPPLY CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 2/1 SIGNAL CIRCUIT SHORTED TO VOLTAGE
CMP 2/1 SIGNAL CIRCUIT SHORTED TO GROUND
CMP 2/1 SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 2/1 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CAMSHAFT POSITION SENSOR 2
CAMSHAFT TONE WHEEL LOOSE/DAMAGED OR MISALIGNED
CAMSHAFT 2/2 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT 2/2 PHASER FAULTY OR INTERMITTENTLY BINDING/STICKING

Possible Causes
POWERTRAIN CONTROL MODULE (PCM)
OIL PRESSURE ISSUE IN CYLINDER HEAD

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK THE ENGINE OIL LEVEL AND CONDITION**
    1. Turn the ignition off.

    NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

    - **LOW ENGINE OIL LEVEL**
    - **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL**
    - **INCORRECT ENGINE OIL VISCOSITY**
    - **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
    - **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

    Were any of the above conditions present?

    Yes

    - Repair as necessary. If the engine oil was not at the proper level, top off the engine oil to the proper specification. Start the engine and allow it to idle for 2 - 3 minutes. Turn the engine off, ignition on, and using the scan tool, erase the DTC. Start the engine and drive the vehicle to verify repair. If the DTC does not return, repair is complete.
    - If the DTC returns, Go To 3

    No

    - Go To 2
2. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on the repair order. Copy DTC and Freeze Frame information.
    3. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    4. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 3

No

- Go To 27

3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

       Are there any 5-Volt Reference, Dual Stage Oil Pump or Oil Pressure related DTCs active or pending?

       Yes

       - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 4
4. **CHECK FOR RELATED CAM SENSOR DTCS**

    Is the P0390 or P0394 DTC also active at this time?

    Yes

    - Go To 5

    No

    - Go To 8
5. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT**

    NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

    1. Turn the ignition off.
    2. Disconnect the CMP Sensor 2 harness connector.
    3. Turn the ignition on.
    4. Measure the voltage on the (F856) 5-Volt Supply circuit at the CMP Sensor 2 harness connector.

       Is the voltage between 4.8 and 5.2 volts?

       Yes

       - Go To 6

       No

       - Repair the (F856) 5-Volt Supply circuit for an open or shorted circuit.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
6. **CHECK THE CMP SENSOR 2 (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. Turn the ignition off.
    2. Disconnect the PCM C2 harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

3. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
4. Measure the resistance of the CMP Sensor 2 (K900) Sensor Ground circuit between the CMP Sensor 2 harness connector and the GPEC Adaptor.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 7

   No

   - Repair the CMP Sensor 2 (K900) Sensor Ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
   1. Remove and exchange the CMP Sensor 2 with the CMP Sensor on the opposite bank.

   NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

   2. Reconnect the PCM C2 and CMP Sensor harness connectors.
   3. Turn the ignition on,
   4. With the scan tool, erase DTCs.
   5. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.
   6. With the scan tool, read DTCs.

   Did the CMP Sensor DTCs for the opposite bank set?

   Yes

   - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 22

8. **CHECK THE CMP SENSOR 2 (K444) SIGNAL 1 CIRCUIT FOR A SHORT TO VOLTAGE**

NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

1. Disconnect the CMP Sensor 2 harness connector.
2. Measure the voltage on the CMP Sensor 2 (K444) Signal 1 circuit in the CMP Sensor 2 harness connector.

   Is the voltage above 5.2 volts?

   Yes

   - Repair the CMP Sensor 2 (K444) Signal 1 circuit for a short to voltage.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK THE CMP SENSOR 2 (K444) SIGNAL 1 CIRCUIT FOR A SHORT TO GROUND**
   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.
   3. Check for continuity between ground and the CMP Sensor 2 (K444) Signal 1 circuit at the CMP Sensor 2 harness connector.

      Is there continuity between ground and the CMP Sensor 2 (K444) Signal 1 circuit?

      Yes

      - Repair the CMP Sensor 2 (K444) Signal 1 circuit for a short to ground.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 10

10. **CHECK FOR THE CMP SENSOR 2 (K444) SIGNAL 1 CIRCUIT SHORTED TO THE CMP SENSOR 2 (K900) SENSOR GROUND CIRCUIT**
    1. Check for continuity between the CMP Sensor 2 (K444) Signal 1 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit at the CMP Sensor 2 harness connector.

       Is there continuity between ground and the CMP Sensor 2 (K444) Signal 1 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit?

       Yes

       - Repair the short between the CMP Sensor 2 (K444) Signal 1 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 11

11. **CHECK THE CMP SENSOR 2 (K444) SIGNAL 1 CIRCUIT FOR AN OPEN/HIGH RESISTANCE**

CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
2. Measure the resistance of the CMP Sensor 2 (K444) Signal 1 circuit between the CMP Sensor 2 harness connector and the GPEC Adaptor.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 12

   No

   - Repair the CMP Sensor 2 (K444) Signal 1 circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

12. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

NOTE: During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

   NOTE: If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.

   Is the oil pressure reading stable and above 16.0 psi?

   Yes

   - Go To 13

   No

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**

1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
3. Start the engine and allow it to idle.
4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

NOTE: The oil pressure reading at the Cylinder Head should be within above 14.0 psi.

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 14

No

- Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK THE CAMSHAFT 2/2 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.
    2. Remove the Camshaft Position Solenoid 2/2.
    3. Inspect the spring loaded spool valve on the Oil Control Valve.

    NOTE: The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.

    4. Push and release the spring loaded spool valve against the return spring with a small punch.

    NOTE: The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.

    Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

    Yes

    - Go To 15

    No

    - Replace the Camshaft 2/2 Oil Control Valve in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

15. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
    1. Remove and exchange the CMP Sensor 2 with the CMP Sensor on the opposite bank.

       NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

    2. Reconnect the PCM C2 and Cam Sensor harness connectors.
    3. Turn the ignition on,
    4. With the scan tool, erase DTCs.
    5. Start the engine and allow it to idle or crank the engine if it will not start.
    6. With the scan tool, read DTCs.

    Did the CMP Sensor DTCs for the opposite bank set as active?

    Yes

    - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 16

16. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    2. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Were any issues found with the CMP Sensor Tone Wheel?

    Yes

    - Replace the Camshaft Assembly in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 17

17. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 18

18. **CHECK THE CAM PHASER AND CAMSHAFT ASSEMBLY**
    1. Check the Cam Phaser to verify it has returned to lock pin.
    2. Put a wrench on the flat of the Camshaft behind the phaser and attempt to move the Camshaft back and forth.

    NOTE: **The Cam Phaser should always return to lock pin when the engine is turned off. If the Cam Phaser is not at lock pin, there will be movement felt between the Camshaft and the Cam Phaser.**

    Is there movement between the Camshaft and Cam Phaser?

    Yes

    - Replace the Cam Phaser in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Go To 19

    No

    - Replace the Cam Phaser and Camshaft in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Go To 19

19. **VERIFY THE REPAIR**

1. With the scan tool, erase DTCs.
2. Test drive the vehicle in accordance with the Freeze Frame data collected.

   Did the DTC return?

   Yes

   - Go To 20

   No

   - Repair is complete.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

20. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
       - Proper connector installation.
       - Damaged connector locks.
       - Corrosion.
       - Other signs of water intrusion.
       - Weather seal damage (if equipped).
       - Bent terminals.
       - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
       - Terminals that have been pushed back into the connector cavity.
       - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Go To 21

        No

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
- Test complete.

21. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

    Did the CMP Sensor DTC return?

    Yes

    - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair is complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

22. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

    1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
    2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
    3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
    4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
    5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

       NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

    Is the oil pressure reading stable and above 16.0 psi?

    Yes

- Go To 23

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

23. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

    NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

    Is the oil pressure reading stable and above 14.0 psi?

    Yes

    - Go To 24

    No

    - Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

24. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

- Go To 25

25. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Go To 26

        No

        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
        - Test complete.

26. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

       Did the CMP Sensor DTC return?

Yes

- Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Repair is complete.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

27. **WIRE HARNESS/CKP SENSOR INSPECTION**
    1. Turn the ignition off.
    2. Disconnect the harness connectors at the PCM and Cam Sensor. Inspect for wire chaffing or rub conditions, spread terminals, terminals pushed out of the wiring connector, bent terminals at the PCM and Cam Sensor, water in the connector cavities, presence of corrosion on the terminals of the connectors or components.
    3. Visually inspect the mounting area of Cam Sensor for debris/damage or a loose sensor. Remove the Cam Sensor and inspect the end of the sensor for signs of damage or debris. Rotate the engine and if possible, inspect the tone wheel for any signs of damage. Reinstall the Cam Sensor and ensure that the sensor is properly installed and torqued to proper specification.

    NOTE: **Due to the fact that this DTC is set by an intermittent loss of the signal, the DTC may be caused by a poor connection at the Cam Sensor or PCM terminals, or a poor signal between the Cam Sensor and tone wheel. Because of this, unplugging and reconnecting the harness connectors, or repositioning the Cam Sensor will often repair the condition that set the DTC.**

    Were any problems found?

    Yes

    - Perform the appropriate repair.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 28

28. **CHECK THE VEHICLE'S REPAIR HISTORY**
    1. Check the history of the vehicle for previous Cam Sensor related DTCs.

    Did the repair history show that the vehicle was previously in the dealership with a Cam Sensor fault?

    Yes

    - If the current DTC being diagnosed is for the **same** engine bank as the DTC that set on the previous visit, perform the diagnostics starting at test step #12 in this diagnostic procedure.

- If the current DTC being diagnosed is for the **opposite** engine bank as the DTC that set on the previous visit, replace the Cam Sensor in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

No

- Swap the Cam Sensor with the Cam Sensor on the opposite bank and clear DTCs. The cause may have been a poor connection at one of the harness connectors. Unplugging and reconnecting the harness connector may resolve the issue. Verify the DTC does not return.

NOTE: **The sensors must be exchanged to aid in determining the possible failure if the vehicle returns to the dealership in the future with another Cam Sensor related DTC.**

- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

P0351-IGNITION COIL 1 PRIMARY CIRCUIT

WHEN MONITORED

- This diagnostic runs continuously with ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Ignition Coil 1 Signal circuit current is less than, or equal to, 0.0 amps for at least 1.2 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
FUSED OUTPUT RELAY CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 1 CONTROL CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 1 CONTROL CIRCUIT SHORTED TO GROUND
IGNITION COIL 1
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
   1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
   2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.

3. With the scan tool, erase all DTCs.
4. Turn the ignition off for a minimum of 10.0 seconds.
5. Turn the ignition on.
6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
7. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are there any ASD DTCs present?

      Yes

      - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

      No

      - Go To 3

3. **CHECK THE RELAY (F343) OUTPUT CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
   1. Disconnect the component harness connector to isolate the 12.0 volt supply circuit.
   2. Connect the positive lead of the load test tool to the 12.0 volt supply circuit at the component harness connector (A). **Note:** refer to the diagram below.
   3. Connect the negative lead of the load test tool to the ground circuit of the Battery or a good chassis ground.
   4. Ensure that the circuit being tested is being powered on. If the 12.0 volt circuit being tested is an ignition feed for example, the ignition must be on. If testing an output from a relay, verify that the relay is energized and on.
   5. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

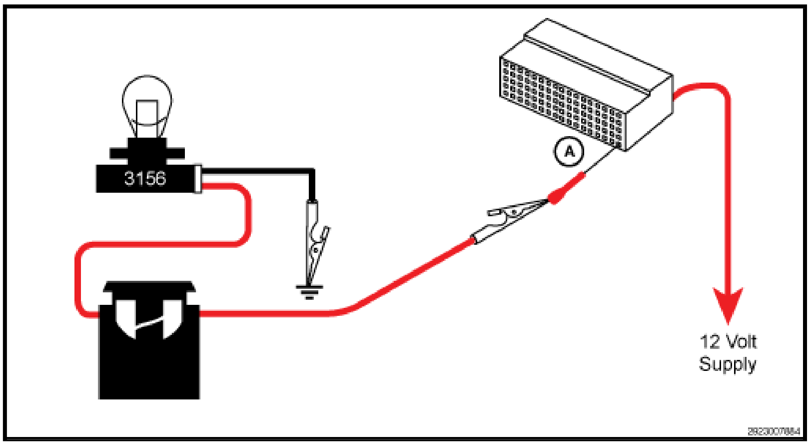
NOTE:	**Why perform a Voltage Drop Test? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**
NOTE:	**A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many**

high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

- Go To 4

No

- Repair the 12.0 volt circuit for an open or high resistance. If the fuse is found to be open, check the circuit for a short to ground.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE IGNITION COIL CONTROL CIRCUIT OPERATION**

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

   1. Using a 12-volt test light connected to a 12.0 volt source, probe the Coil 1 (K19) Control circuit at the Ignition Coil harness connector.
   2. Crank the engine for 5.0 seconds while observing the test light.

   What is the condition of the test light while cranking the engine?

   Brightly blinking

   - Go To 5

   ON constantly

   - Go To 6

   OFF constantly

   - Go To 7

5. **CHECK THE CONDITION OF THE SPARK PLUG**
   1. Turn the ignition off.
   2. Remove the Spark Plug(s) in accordance with the Service Information.
   3. Inspect the Spark Plug(s) for the following conditions:
      - Cracks
      - Carbon Tracking
      - Foreign Material
      - Gap size out of specifications
      - Loose or broken electrode

   Were any of the above conditions present?

   Yes

   - Replace the Spark Plug in accordance with the Service Information.

     NOTE: **If carbon tracking is found on the Spark Plug, inspect the boot on the Ignition Coil for signs of damage and replace if necessary.**

   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Replace the Ignition Coil and Spark Plug in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **ISOLATE AND CHECK THE IGNITION COIL 1 (K19) CONTROL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

    NOTE: **There should be no continuity between ground and the circuit being tested.**

    Is there continuity between ground and the circuit being tested?

    Yes

    - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 8
7. **ISOLATE AND CHECK THE IGNITION COIL 1 (K19) CONTROL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

        NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

Is the resistance below 3.0 Ohms?

Yes

- Go To 8

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **DETERMINE IF THE IGNITION COIL IS THE CAUSE OF THE PCM DRIVER FAILURE**

   NOTE: **An internally shorted or damaged secondary coil circuit may be the cause of the PCM coil driver failure. Do not replace the PCM without first determining if the Ignition Coil is the cause of the failure.**

   1. Remove the Ignition Coil that is controlled by the coil driver setting the DTC.
   2. Install the Ignition Coil onto another coil location that did not have a DTC set against it.
   3. Turn the ignition on.
   4. With the scan tool, erase DTCs.
   5. Start and run the engine for up to one minute.

      NOTE: **If the engine will not start, crank the engine three times for 10 seconds.**

   6. With a scan tool, read DTCs.

   Did a correlating fault set for the new coil location?

   Yes

   - Replace the Ignition Coil in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
   - Replace and program the Powertrain Control Module in accordance with the Service Information.

     Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .

   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.

- Damaged connector locks.
- Corrosion.
- Other signs of water intrusion.
- Weather seal damage (if equipped).
- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

   Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0352-IGNITION COIL 2 PRIMARY CIRCUIT

WHEN MONITORED

- This diagnostic runs continuously with ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Ignition Coil 2 Signal circuit current is less than, or equal to, 0.0 amps for at least 1.2 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
FUSED OUTPUT RELAY CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 2 CONTROL CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 2 CONTROL CIRCUIT SHORTED TO GROUND
IGNITION COIL 2
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

        Are there any ASD DTCs present?

        Yes

        - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

        No

        - Go To 3
3. **CHECK THE RELAY (F343) OUTPUT CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
    1. Disconnect the component harness connector to isolate the 12.0 volt supply circuit.
    2. Connect the positive lead of the load test tool to the 12.0 volt supply circuit at the component harness connector (A). **Note:** refer to the diagram below.

3. Connect the negative lead of the load test tool to the ground circuit of the Battery or a good chassis ground.
4. Ensure that the circuit being tested is being powered on. If the 12.0 volt circuit being tested is an ignition feed for example, the ignition must be on. If testing an output from a relay, verify that the relay is energized and on.
5. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

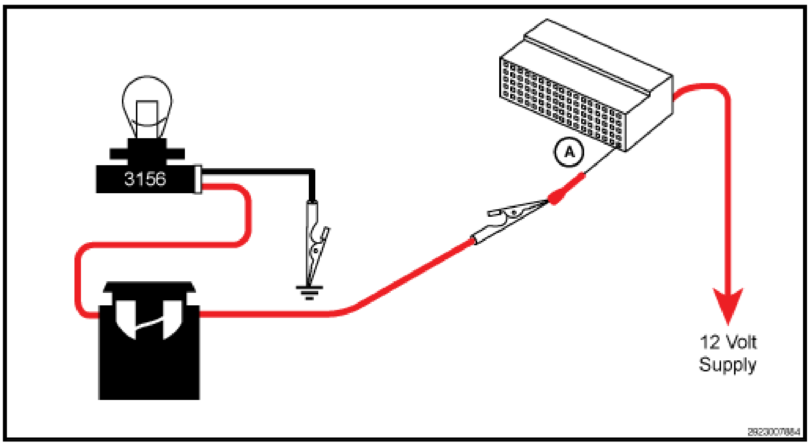
NOTE: **Why perform a Voltage Drop Test? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to** **CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to **CIRCUIT LOAD TESTING PROCEDURES .**



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 4

   No

   - Repair the 12.0 volt circuit for an open or high resistance. If the fuse is found to be open, check the circuit for a short to ground.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE IGNITION COIL CONTROL CIRCUIT OPERATION**

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

1. Using a 12-volt test light connected to a 12.0 volt source, probe the Coil 2 (K17) Control circuit at the Ignition Coil harness connector.
2. Crank the engine for 5.0 seconds while observing the test light.

   What is the condition of the test light while cranking the engine?

   Brightly blinking

   - Go To 5

   ON constantly

- Go To 6

OFF constantly

- Go To 7

5. **CHECK THE CONDITION OF THE SPARK PLUG**
   1. Turn the ignition off.
   2. Remove the Spark Plug(s) in accordance with the Service Information.
   3. Inspect the Spark Plug(s) for the following conditions:
      - Cracks
      - Carbon Tracking
      - Foreign Material
      - Gap size out of specifications
      - Loose or broken electrode

   Were any of the above conditions present?

   Yes

   - Replace the Spark Plug in accordance with the Service Information.

     NOTE: **If carbon tracking is found on the Spark Plug, inspect the boot on the Ignition Coil for signs of damage and replace if necessary.**

   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Replace the Ignition Coil and Spark Plug in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
6. **ISOLATE AND CHECK THE IGNITION COIL 2 (K17) CONTROL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 8

7. **ISOLATE AND CHECK THE IGNITION COIL 2 (K17) CONTROL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

   CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

      NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 8

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
8. **DETERMINE IF THE IGNITION COIL IS THE CAUSE OF THE PCM DRIVER FAILURE**

   NOTE: **An internally shorted or damaged secondary coil circuit may be the cause of the PCM coil driver failure. Do not replace the PCM without first determining if the Ignition Coil is the cause of the failure.**

   1. Remove the Ignition Coil that is controlled by the coil driver setting the DTC.
   2. Install the Ignition Coil onto another coil location that did not have a DTC set against it.
   3. Turn the ignition on.
   4. With the scan tool, erase DTCs.
   5. Start and run the engine for up to one minute.

      NOTE: **If the engine will not start, crank the engine three times for 10 seconds.**

6. With a scan tool, read DTCs.

   Did a correlating fault set for the new coil location?

   Yes

   - Replace the Ignition Coil in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
   - Replace and program the Powertrain Control Module in accordance with the Service Information.

     Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .

   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.

   6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   9. With the scan tool, erase DTCs.
   10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
   11. With the scan tool, read DTCs.

       Did the DTC return?

       Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0353-IGNITION COIL 3 PRIMARY CIRCUIT

WHEN MONITORED

- This diagnostic runs continuously with ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Ignition Coil 3 Signal circuit current is less than, or equal to, 0.0 amps for at least 1.2 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
FUSED OUTPUT RELAY CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 3 CONTROL CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 3 CONTROL CIRCUIT SHORTED TO GROUND
IGNITION COIL 3
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK FOR OTHER DTCS**
   1. Refer to the recorded DTCs.

      Are there any ASD DTCs present?

      Yes

      - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

      No

      - Go To 3
3. **CHECK THE RELAY (F343) OUTPUT CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
   1. Disconnect the component harness connector to isolate the 12.0 volt supply circuit.
   2. Connect the positive lead of the load test tool to the 12.0 volt supply circuit at the component harness connector (A). **Note:** refer to the diagram below.
   3. Connect the negative lead of the load test tool to the ground circuit of the Battery or a good chassis ground.
   4. Ensure that the circuit being tested is being powered on. If the 12.0 volt circuit being tested is an ignition feed for example, the ignition must be on. If testing an output from a relay, verify that the relay is energized and on.
   5. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

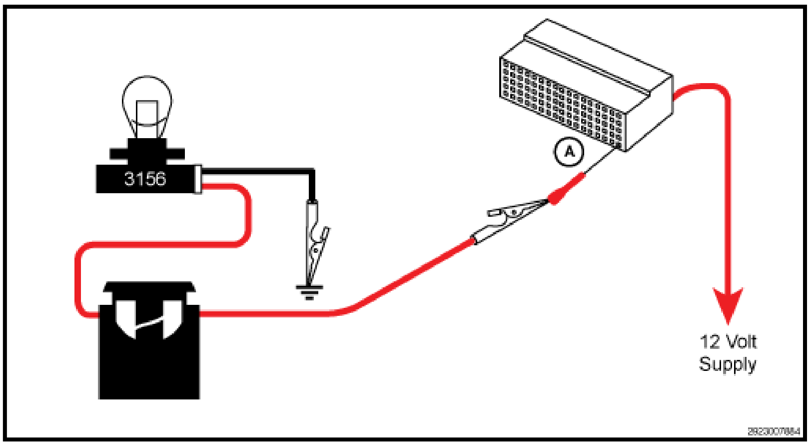
NOTE: **Why perform a Voltage Drop Test? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 4

   No

   - Repair the 12.0 volt circuit for an open or high resistance. If the fuse is found to be open, check the circuit for a short to ground.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE IGNITION COIL CONTROL CIRCUIT OPERATION**

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

1. Using a 12-volt test light connected to a 12.0 volt source, probe the Coil 3 (K18) Control circuit at the Ignition Coil harness connector.
2. Crank the engine for 5.0 seconds while observing the test light.

What is the condition of the test light while cranking the engine?

Brightly blinking

- Go To 5

ON constantly

- Go To 6

OFF constantly

- Go To 7

5. **CHECK THE CONDITION OF THE SPARK PLUG**
1. Turn the ignition off.
2. Remove the Spark Plug(s) in accordance with the Service Information.
3. Inspect the Spark Plug(s) for the following conditions:
   - Cracks
   - Carbon Tracking
   - Foreign Material
   - Gap size out of specifications
   - Loose or broken electrode

Were any of the above conditions present?

Yes

- Replace the Spark Plug in accordance with the Service Information.

NOTE: **If carbon tracking is found on the Spark Plug, inspect the boot on the Ignition Coil for signs of damage and replace if necessary.**

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Replace the Ignition Coil and Spark Plug in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **ISOLATE AND CHECK THE IGNITION COIL 3 (K18) CONTROL CIRCUIT FOR A SHORT TO GROUND**

1. The ignition must be off when checking a circuit for continuity to ground.
2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
3. Connect the negative lead of the DVOM to a known good ground.
4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 8

7. **ISOLATE AND CHECK THE IGNITION COIL 3 (K18) CONTROL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

Is the resistance below 3.0 Ohms?

Yes

- Go To 8

No

- Repair the circuit for an open or high resistance.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **DETERMINE IF THE IGNITION COIL IS THE CAUSE OF THE PCM DRIVER FAILURE**

   NOTE: **An internally shorted or damaged secondary coil circuit may be the cause of the PCM coil driver failure. Do not replace the PCM without first determining if the Ignition Coil is the cause of the failure.**

   1. Remove the Ignition Coil that is controlled by the coil driver setting the DTC.
   2. Install the Ignition Coil onto another coil location that did not have a DTC set against it.
   3. Turn the ignition on.
   4. With the scan tool, erase DTCs.
   5. Start and run the engine for up to one minute.

      NOTE: **If the engine will not start, crank the engine three times for 10 seconds.**

   6. With a scan tool, read DTCs.

   Did a correlating fault set for the new coil location?

   Yes

   - Replace the Ignition Coil in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
   - Replace and program the Powertrain Control Module in accordance with the Service Information.

     Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.

- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0354-IGNITION COIL 4 PRIMARY CIRCUIT

WHEN MONITORED

- This diagnostic runs continuously with ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Ignition Coil 4 Signal circuit current is less than, or equal to, 0.0 amps for at least 1.2 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
FUSED OUTPUT RELAY CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 4 CONTROL CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 4 CONTROL CIRCUIT SHORTED TO GROUND
IGNITION COIL 4
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

        Are there any ASD DTCs present?

        Yes

        - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

        No

        - Go To 3
3. **CHECK THE RELAY (F343) OUTPUT CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
    1. Disconnect the component harness connector to isolate the 12.0 volt supply circuit.
    2. Connect the positive lead of the load test tool to the 12.0 volt supply circuit at the component harness connector (A). **Note:** refer to the diagram below.
    3. Connect the negative lead of the load test tool to the ground circuit of the Battery or a good chassis ground.
    4. Ensure that the circuit being tested is being powered on. If the 12.0 volt circuit being tested is an ignition feed for example, the ignition must be on. If testing an output from a relay, verify that the relay is energized and on.
    5. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

NOTE: **Why perform a Voltage Drop Test? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps**

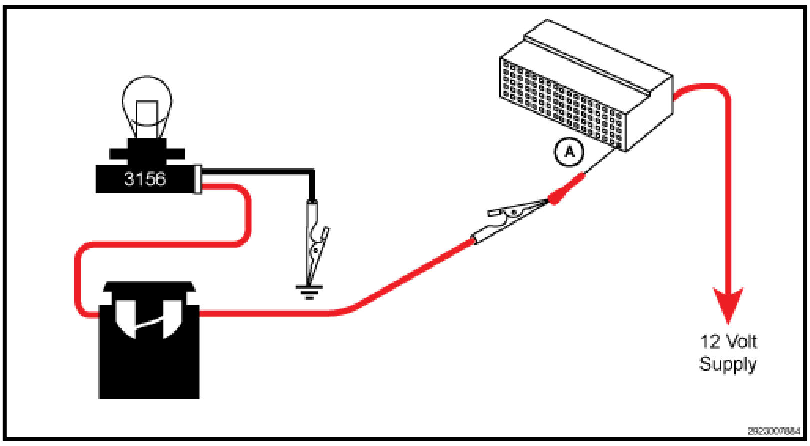
of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .

NOTE: A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.

NOTE: Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:

1. Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.
2. Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.
3. The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.

NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

Is the load test bulb illuminated and bright?

Yes

- Go To 4

No

- Repair the 12.0 volt circuit for an open or high resistance. If the fuse is found to be open, check the circuit for a short to ground.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE IGNITION COIL CONTROL CIRCUIT OPERATION**

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

1. Using a 12-volt test light connected to a 12.0 volt source, probe the Coil 4 (K15) Control circuit at the Ignition Coil harness connector.
2. Crank the engine for 5.0 seconds while observing the test light.

What is the condition of the test light while cranking the engine?

Brightly blinking

- Go To 5

ON constantly

- Go To 6

OFF constantly

- Go To 7

5. **CHECK THE CONDITION OF THE SPARK PLUG**
   1. Turn the ignition off.
   2. Remove the Spark Plug(s) in accordance with the Service Information.
   3. Inspect the Spark Plug(s) for the following conditions:
      - Cracks
      - Carbon Tracking
      - Foreign Material
      - Gap size out of specifications
      - Loose or broken electrode

Were any of the above conditions present?

Yes

- Replace the Spark Plug in accordance with the Service Information.

NOTE: **If carbon tracking is found on the Spark Plug, inspect the boot on the Ignition Coil for signs of damage and replace if necessary.**

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Replace the Ignition Coil and Spark Plug in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **ISOLATE AND CHECK THE IGNITION COIL 4 (K15) CONTROL CIRCUIT FOR A SHORT TO GROUND**
   1. The ignition must be off when checking a circuit for continuity to ground.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Connect the negative lead of the DVOM to a known good ground.
   4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

   NOTE: **There should be no continuity between ground and the circuit being tested.**

   Is there continuity between ground and the circuit being tested?

   Yes

   - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 8
7. **ISOLATE AND CHECK THE IGNITION COIL 4 (K15) CONTROL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

   CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 8

   No

   - Repair the circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **DETERMINE IF THE IGNITION COIL IS THE CAUSE OF THE PCM DRIVER FAILURE**

   NOTE: An internally shorted or damaged secondary coil circuit may be the cause of the PCM coil driver failure. Do not replace the PCM without first determining if the Ignition Coil is the cause of the failure.

   1. Remove the Ignition Coil that is controlled by the coil driver setting the DTC.
   2. Install the Ignition Coil onto another coil location that did not have a DTC set against it.
   3. Turn the ignition on.
   4. With the scan tool, erase DTCs.
   5. Start and run the engine for up to one minute.

      NOTE: If the engine will not start, crank the engine three times for 10 seconds.

   6. With a scan tool, read DTCs.

      Did a correlating fault set for the new coil location?

      Yes

      - Replace the Ignition Coil in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
      - Replace and program the Powertrain Control Module in accordance with the Service Information.

        Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .

      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.

3. Disconnect all related in-line harness connections (if equipped).
4. Disconnect the related component harness connectors.
5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
   - Proper connector installation.
   - Damaged connector locks.
   - Corrosion.
   - Other signs of water intrusion.
   - Weather seal damage (if equipped).
   - Bent terminals.
   - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
   - Terminals that have been pushed back into the connector cavity.
   - Check for spread terminals and verify proper terminal tension.

   Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - The wiring or poor connection problem has been repaired.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0355-IGNITION COIL 5 PRIMARY CIRCUIT

WHEN MONITORED

- This diagnostic runs continuously with ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Ignition Coil 5 Signal circuit current is less than, or equal to, 0.0 amps for at least 1.2 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
FUSED OUTPUT RELAY CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 5 CONTROL CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 5 CONTROL CIRCUIT SHORTED TO GROUND
IGNITION COIL 5
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 2

    No

    - Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .
2. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

        Are there any ASD DTCs present?

        Yes

        - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

        No

        - Go To 3
3. **CHECK THE RELAY (F343) OUTPUT CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**

1. Disconnect the component harness connector to isolate the 12.0 volt supply circuit.
2. Connect the positive lead of the load test tool to the 12.0 volt supply circuit at the component harness connector (A). **Note:** refer to the diagram below.
3. Connect the negative lead of the load test tool to the ground circuit of the Battery or a good chassis ground.
4. Ensure that the circuit being tested is being powered on. If the 12.0 volt circuit being tested is an ignition feed for example, the ignition must be on. If testing an output from a relay, verify that the relay is energized and on.
5. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

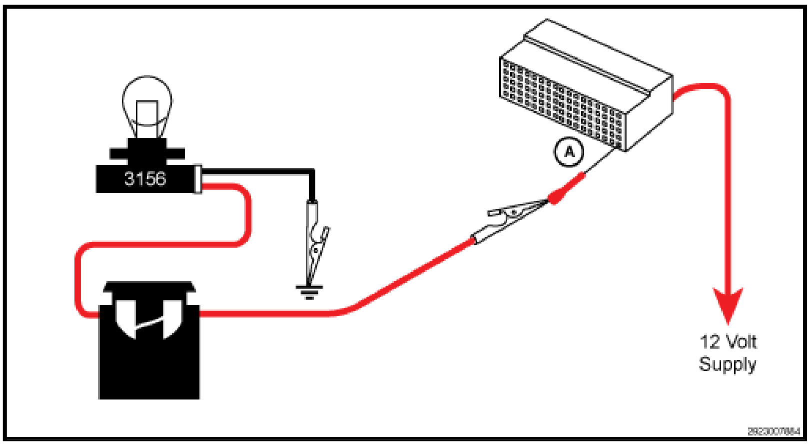
NOTE: **Why perform a Voltage Drop Test? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to** **CIRCUIT LOAD TESTING PROCEDURES .**

NOTE: **A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE: **Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to **CIRCUIT LOAD TESTING PROCEDURES .**



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 4

   No

   - Repair the 12.0 volt circuit for an open or high resistance. If the fuse is found to be open, check the circuit for a short to ground.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

4. **CHECK THE IGNITION COIL CONTROL CIRCUIT OPERATION**

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

1. Using a 12-volt test light connected to a 12.0 volt source, probe the Coil 5 (K16) Control circuit at the Ignition Coil harness connector.
2. Crank the engine for 5.0 seconds while observing the test light.

   What is the condition of the test light while cranking the engine?

   Brightly blinking

   - Go To 5

   ON constantly

- Go To 6

OFF constantly

- Go To 7

5. **CHECK THE CONDITION OF THE SPARK PLUG**
    1. Turn the ignition off.
    2. Remove the Spark Plug(s) in accordance with the Service Information.
    3. Inspect the Spark Plug(s) for the following conditions:
        - Cracks
        - Carbon Tracking
        - Foreign Material
        - Gap size out of specifications
        - Loose or broken electrode

    Were any of the above conditions present?

    Yes

    - Replace the Spark Plug in accordance with the Service Information.

NOTE:	If carbon tracking is found on the Spark Plug, inspect the boot on the Ignition Coil for signs of damage and replace if necessary.

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Replace the Ignition Coil and Spark Plug in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
6. **ISOLATE AND CHECK THE IGNITION COIL 5 (K16) CONTROL CIRCUIT FOR A SHORT TO GROUND**
    1. The ignition must be off when checking a circuit for continuity to ground.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Connect the negative lead of the DVOM to a known good ground.
    4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

NOTE:	There should be no continuity between ground and the circuit being tested.

    Is there continuity between ground and the circuit being tested?

    Yes

    - Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 8

7. **ISOLATE AND CHECK THE IGNITION COIL 5 (K16) CONTROL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. The ignition must be off when checking the continuity of a circuit.
    2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
    3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
    4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
    5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

Is the resistance below 3.0 Ohms?

Yes

- Go To 8

No

- Repair the circuit for an open or high resistance.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **DETERMINE IF THE IGNITION COIL IS THE CAUSE OF THE PCM DRIVER FAILURE**

NOTE: **An internally shorted or damaged secondary coil circuit may be the cause of the PCM coil driver failure. Do not replace the PCM without first determining if the Ignition Coil is the cause of the failure.**

1. Remove the Ignition Coil that is controlled by the coil driver setting the DTC.
2. Install the Ignition Coil onto another coil location that did not have a DTC set against it.
3. Turn the ignition on.
4. With the scan tool, erase DTCs.
5. Start and run the engine for up to one minute.

NOTE: **If the engine will not start, crank the engine three times for 10 seconds.**

6. With a scan tool, read DTCs.

   Did a correlating fault set for the new coil location?

   Yes

   - Replace the Ignition Coil in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
   - Replace and program the Powertrain Control Module in accordance with the Service Information.

     Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .

   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
   1. Perform any Service Bulletins that apply.
   2. Disconnect all PCM harness connectors.
   3. Disconnect all related in-line harness connections (if equipped).
   4. Disconnect the related component harness connectors.
   5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
      - Proper connector installation.
      - Damaged connector locks.
      - Corrosion.
      - Other signs of water intrusion.
      - Weather seal damage (if equipped).
      - Bent terminals.
      - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
      - Terminals that have been pushed back into the connector cavity.
      - Check for spread terminals and verify proper terminal tension.

      Repair any conditions that are found.

   6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
   7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
   8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
   9. With the scan tool, erase DTCs.
   10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
   11. With the scan tool, read DTCs.

       Did the DTC return?

       Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0356-IGNITION COIL 6 PRIMARY CIRCUIT

WHEN MONITORED

- This diagnostic runs continuously with ignition on.

SET CONDITION

- The Powertrain Control Module (PCM) detects that the Ignition Coil 6 Signal circuit current is less than, or equal to, 0.0 amps for at least 1.2 seconds.

DEFAULT ACTION

- The MIL will illuminate.

POSSIBLE CAUSES

Possible Causes
FUSED OUTPUT RELAY CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 6 CONTROL CIRCUIT OPEN/HIGH RESISTANCE
IGNITION COIL 6 CONTROL CIRCUIT SHORTED TO GROUND
IGNITION COIL 6
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **READ AND RECORD DTCS AND ENVIRONMENTAL DATA - ERASE DTCS AND CHECK FOR THE DTC TO RETURN**
    1. With the scan tool, read DTCs in all Electronic Control Units (ECUs) and record on the repair order.
    2. For future reference, with the scan tool, run and save a vehicle Scan Report and all related recorded data.
    3. With the scan tool, erase all DTCs.
    4. Turn the ignition off for a minimum of 10.0 seconds.
    5. Turn the ignition on.
    6. Using the When Monitored and Set Conditions above and recorded data, operate the vehicle in the conditions that set the DTC.
    7. With the scan tool, read DTCs.

    Did the DTC return?

Yes

- Go To 2

No

- Perform the INTERMITTENT CONDITION diagnostic procedure. Refer to **INTERMITTENT CONDITION** .

2. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

       Are there any ASD DTCs present?

       Yes

       - Perform the applicable diagnostic procedure(s). Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 3

3. **CHECK THE RELAY (F343) OUTPUT CIRCUIT FOR HIGH RESISTANCE BY LOAD TESTING THE CIRCUIT**
    1. Disconnect the component harness connector to isolate the 12.0 volt supply circuit.
    2. Connect the positive lead of the load test tool to the 12.0 volt supply circuit at the component harness connector (A). **Note:** refer to the diagram below.
    3. Connect the negative lead of the load test tool to the ground circuit of the Battery or a good chassis ground.
    4. Ensure that the circuit being tested is being powered on. If the 12.0 volt circuit being tested is an ignition feed for example, the ignition must be on. If testing an output from a relay, verify that the relay is energized and on.
    5. The bulb on the load test tool should be illuminated and bright if there is no resistance in the circuitry.

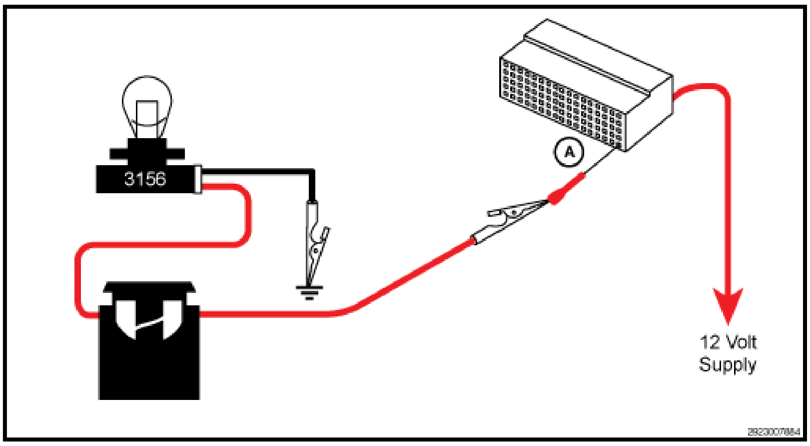
NOTE:	**Why perform a Voltage Drop Test? A load test is used to determine if a circuit is capable of carrying the amperage needed to perform properly. The 3156 bulb in the load tool illustrated, is a simple but effective method of testing circuit functionality. A 3156 Bulb has approximately 6.0 Ohms of resistance when the bulb is powered and draws approximately 2.0 amps of current. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .**

NOTE:	**A 12-volt test light can be substituted for the load test tool, but only if the test light draws enough current to effectively load test the circuit. Many high impedance test lights draw very little amperage (less than 0.1 amps) and are not reliable to load test a circuit. To perform a proper load test of a circuit, the tool being used should draw more than approximately 0.75 amps.**

NOTE:	**Why perform a Voltage Drop Test? To verify with certainty there is not any resistance in the circuit being tested, perform a simple voltage drop test across the 3156 bulb of the load test tool. To do so perform the following:**

1. **Connect the leads of a DVOM to the alligator clips on the load test tool while the load test tool is connected in series with the circuit.**
2. **Compare the voltage drop across the bulb to the voltage reading across the Battery terminals.**
3. **The voltage dropped across the bulb should be equal to the voltage reading across the Battery terminals if there is no resistance in the circuit being tested.**

Example: 2.0 Ohms of resistance in the circuit being tested will cause the voltage measurement across the bulb to be 25% less than when compared to Battery voltage. The reason for this is that the 2.0 Ohms in the circuit makes up 25% of the total circuit resistance of 8.0 Ohms. Read the CIRCUIT LOAD TESTING PROCEDURE for information on building a simple load test tool and for additional load testing information and alternative methods of load testing or voltage drop testing a circuit. Refer to CIRCUIT LOAD TESTING PROCEDURES .



CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   NOTE: **Compare the brightness of the bulb in the load test tool to that of a direct connection to Battery.**

   Is the load test bulb illuminated and bright?

   Yes

   - Go To 4

   No

   - Repair the 12.0 volt circuit for an open or high resistance. If the fuse is found to be open, check the circuit for a short to ground.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

4. **CHECK THE IGNITION COIL CONTROL CIRCUIT OPERATION**

WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

   1. Using a 12-volt test light connected to a 12.0 volt source, probe the Coil 6 (K10) Control circuit at the Ignition Coil harness connector.
   2. Crank the engine for 5.0 seconds while observing the test light.

   What is the condition of the test light while cranking the engine?

   Brightly blinking

   - Go To 5

   ON constantly

   - Go To 6

   OFF constantly

   - Go To 7

5. **CHECK THE CONDITION OF THE SPARK PLUG**
   1. Turn the ignition off.
   2. Remove the Spark Plug(s) in accordance with the Service Information.
   3. Inspect the Spark Plug(s) for the following conditions:
      - Cracks
      - Carbon Tracking
      - Foreign Material
      - Gap size out of specifications
      - Loose or broken electrode

   Were any of the above conditions present?

   Yes

   - Replace the Spark Plug in accordance with the Service Information.

     NOTE: **If carbon tracking is found on the Spark Plug, inspect the boot on the Ignition Coil for signs of damage and replace if necessary.**

   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Replace the Ignition Coil and Spark Plug in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **ISOLATE AND CHECK THE IGNITION COIL 6 (K10) CONTROL CIRCUIT FOR A SHORT TO GROUND**

1. The ignition must be off when checking a circuit for continuity to ground.
2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and every component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
3. Connect the negative lead of the DVOM to a known good ground.
4. With the positive lead of the DVOM, probe the circuit being tested at the component harness connector and check for continuity between the circuit and ground.

NOTE: **There should be no continuity between ground and the circuit being tested.**

Is there continuity between ground and the circuit being tested?

Yes

- Repair the circuit for a short to ground. Use the appropriate wiring diagram as a guide to trace the circuit and look for any in-line connectors to help isolate the location of the short.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 8

7. **ISOLATE AND CHECK THE IGNITION COIL 6 (K10) CONTROL CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. The ignition must be off when checking the continuity of a circuit.
   2. Isolate the circuit by disconnecting the Electronic Control Unit (ECU) and the component harness connector containing the circuit being tested. **Note:** Use the appropriate wiring diagram as a guide to follow the path of the circuit.
   3. Before measuring the resistance of any circuit, first measure the resistance between the two leads of the DVOM. **Note:** The meter leads can add resistance to the measurement value.
   4. Connect one lead of the DVOM to the circuit being tested at the component harness connector.
   5. Connect the other lead to the circuit being tested at the GPEC Adaptor and measure the resistance of the circuit.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   1. If it is necessary to probe a terminal at a PCM harness connector, connect the (special tool #10436, Adapter, GPEC Diagnostic) to the appropriate PCM harness connector.

   NOTE: **IMPORTANT - The GPEC Diagnostic Adaptor can add up to 1.5 Ohms of resistance to the circuit.**

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 8

   No

   - Repair the circuit for an open or high resistance.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

8. **DETERMINE IF THE IGNITION COIL IS THE CAUSE OF THE PCM DRIVER FAILURE**

    NOTE: **An internally shorted or damaged secondary coil circuit may be the cause of the PCM coil driver failure. Do not replace the PCM without first determining if the Ignition Coil is the cause of the failure.**

    1. Remove the Ignition Coil that is controlled by the coil driver setting the DTC.
    2. Install the Ignition Coil onto another coil location that did not have a DTC set against it.
    3. Turn the ignition on.
    4. With the scan tool, erase DTCs.
    5. Start and run the engine for up to one minute.

        NOTE: **If the engine will not start, crank the engine three times for 10 seconds.**

    6. With a scan tool, read DTCs.

    Did a correlating fault set for the new coil location?

    Yes

    - Replace the Ignition Coil in accordance with the Service Information. Refer to **COIL, IGNITION, REMOVAL AND INSTALLATION** .
    - Replace and program the Powertrain Control Module in accordance with the Service Information.

        Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 9

9. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.

- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Replace and program the Powertrain Control Module (PCM) in accordance with the Service Information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- The wiring or poor connection problem has been repaired.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0365-CAMSHAFT POSITION SENSOR CIRCUIT - BANK 1 SENSOR 2

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

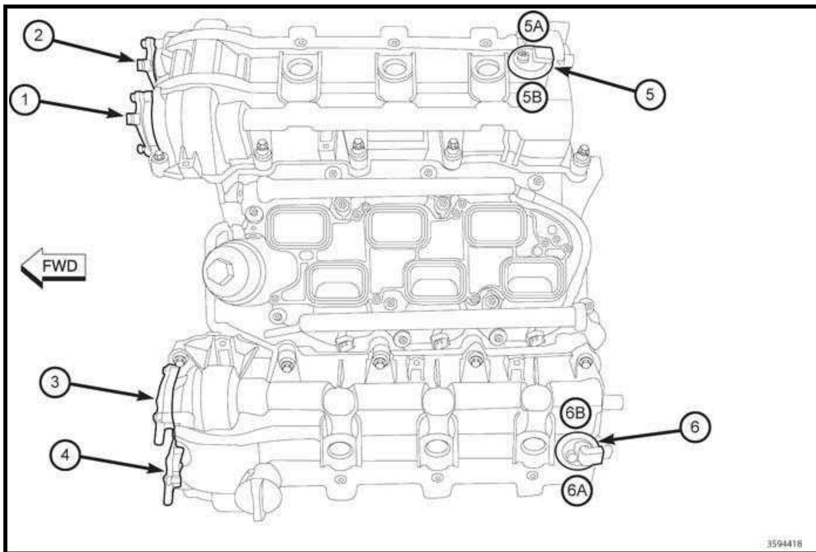
The Camshaft Position (CMP) Sensor circuits consist of a Powertrain Control Module (PCM) supplied 5-Volt reference circuit, low reference circuit, and an output signal circuit. The CMP Sensor detects magnetic flux from the peaks and valleys between the magnets of the tone wheel attached to the camshaft. As each magnet rotates past the CMP Sensor, the resulting change in the magnetic field is used by the sensor electronics to produce a digital output pulse. The sensor returns a digital ON/OFF DC voltage pulse of varying frequency output pulses per Camshaft revolution that represent an image of the camshaft tone wheel. The frequency of the CMP Sensor output depends on the velocity of the camshaft. The PCM decodes the tooth pattern to identify camshaft position. This information is then used to sequence the ignition timing and fuel injection events for the engine. The PCM also uses CMP Sensor output information to determine the camshaft relative position to the Crankshaft, to control the CMP Actuator operation if equipped.

NOTE: **The engine may still start even if either the Crankshaft Position (CKP) Sensor or CMP fails. The PCM eventually sorts out engine position and starts the vehicle on just one of these two inputs. However, there is a slight delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and tables below indicating the CMP Sensor, Position Solenoid/Phaser and DTC orientation).

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	**CALLOUT #**	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERFORMANCE DTCS**
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

3.2L / 3.6L VVT Component Locations			
CALLOUT	**DESCRIPTION**	**CALLOUT**	**DESCRIPTION**
1	CMP Position Solenoid - Bank 1 Position 1 (INTAKE)	5A	CMP Sensor - Bank 1 Sensor 1 (EXHAUST)
2	CMP Position Solenoid - Bank 1 Position 2 (EXHAUST)	5B	CMP Sensor - Bank 1 Sensor 2 (INTAKE)
3	CMP Position Solenoid - Bank 2 Position 1 (INTAKE)	6	Bank 2 Camshaft Sensor
4	CMP Position Solenoid - Bank 2 Position 2 (EXHAUST)	6A	CMP Sensor - Bank 2 Sensor 1 (EXHAUST)
5	Bank 1 Camshaft Sensor	6B	CMP Sensor - Bank 2 Sensor 2 (INTAKE)



WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine cranking and with the engine running.
- Battery voltage is above approximately 11.0 volts.

SET CONDITION

- During cranking, at least 2.5 seconds have elapsed with a Crankshaft Position Sensor signal present but no Camshaft Position Sensor signal.

- With the engine running, the Camshaft Position Sensor signal is lost for at least 0.4 seconds with a Crankshaft Position Sensor signal present.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
LOW ENGINE OIL LEVEL
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT OPEN
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
5-VOLT SUPPLY CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 1/2 SIGNAL CIRCUIT SHORTED TO VOLTAGE
CMP 1/2 SIGNAL CIRCUIT SHORTED TO GROUND
CMP 1/2 SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 1/2 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CAMSHAFT POSITION SENSOR 1
CAMSHAFT TONE WHEEL LOOSE/DAMAGED OR MISALIGNED
CAMSHAFT PHASER 1/1 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT PHASER 1/1 FAULTY OR INTERMITTENTLY BINDING/STICKING
OIL PRESSURE ISSUE IN CYLINDER HEAD
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK THE ENGINE OIL LEVEL AND CONDITION**
    1. Turn the igntion off.

NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

- **LOW ENGINE OIL LEVEL**
- **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL**
- **INCORRECT ENGINE OIL VISCOSITY**
- **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

Were any of the above conditions present?

Yes

- Repair as necessary. If the engine oil was not at the proper level, top off the engine oil to the proper specification. Start the engine and allow it to idle for 2 - 3 minutes. Turn the engine off, ignition on, and using the scan tool, erase the DTC. Start the engine and drive the vehicle to verify repair. If the DTC does not return, repair is complete.
- If the DTC returns, Go To 3

No

- Go To 2

2. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on the repair order. Copy DTC and Freeze Frame information.
    3. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    4. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 3

    No

    - Go To 27

3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

    Are there any 5-Volt Reference, Dual Stage Oil Pump or Oil Pressure related DTCs active or pending?

    Yes

    - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

    No

    - Go To 4

4. **CHECK FOR RELATED CAM SENSOR DTCS**

    Is the P0340 or P0344 DTC also active at this time?

    Yes

    - Go To 5

    No

- Go To 8

5. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT**

   NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

   1. Turn the ignition off.
   2. Disconnect the CMP Sensor 1 harness connector.
   3. Turn the ignition on.
   4. Measure the voltage on the (F856) 5-Volt Supply circuit at the CMP Sensor 1 harness connector.

      Is the voltage between 4.8 and 5.2 volts?

      Yes

      - Go To 6

      No

      - Repair the (F856) 5-Volt Supply circuit for an open or shorted circuit.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE CMP SENSOR 1 (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.

      CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

   3. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
   4. Measure the resistance of the CMP Sensor 1 (K900) Sensor Ground circuit between the CMP Sensor 1 harness connector and the GPEC Adaptor.

      Is the resistance below 3.0 Ohms?

      Yes

      - Go To 7

      No

      - Repair the CMP Sensor 1 (K900) Sensor Ground circuit for an open or high resistance.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
   1. Remove and exchange the CMP Sensor 1 with the CMP Sensor on the opposite bank.

      NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed**

every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.

2. Reconnect the PCM C2 and CMP Sensor harness connectors.
3. Turn the ignition on,
4. With the scan tool, erase DTCs.
5. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.
6. With the scan tool, read DTCs.

   Did the CMP Sensor DTCs for the opposite bank set?

   Yes

   - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 22

8. **CHECK THE CMP SENSOR 1 (K441) POSITION SIGNAL 2 CIRCUIT FOR A SHORT TO VOLTAGE**

   NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

   1. Disconnect the CMP Sensor 1 harness connector.
   2. Measure the voltage on the CMP Sensor 1 (K441) Position Signal 2 circuit in the CMP Sensor 1 harness connector.

      Is the voltage above 5.2 volts?

      Yes

      - Repair the CMP Sensor 1 (K441) Position Signal 2 circuit for a short to voltage.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 9

9. **CHECK THE CMP SENSOR 1 (K441) POSITION SIGNAL 2 CIRCUIT FOR A SHORT TO GROUND**

   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.
   3. Check for continuity between ground and the CMP Sensor 1 (K441) Position Signal 2 circuit at the CMP Sensor 1 harness connector.

Is there continuity between ground and the CMP Sensor 1 (K441) Position Signal 2 circuit?

Yes

- Repair the CMP Sensor 1 (K441) Position Signal 2 circuit for a short to ground.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 10

10. **CHECK FOR THE CMP SENSOR 1 (K441) POSITION SIGNAL 2 CIRCUIT SHORTED TO THE CMP SENSOR 1 (K900) SENSOR GROUND CIRCUIT**
    1. Check for continuity between the CMP Sensor 1 (K441) Position Signal 2 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit at the CMP Sensor 1 harness connector.

       Is there continuity between ground and the CMP Sensor 1 (K441) Position Signal 2 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit?

       Yes

       - Repair the short between the CMP Sensor 1 (K441) Position Signal 2 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 11

11. **CHECK THE CMP SENSOR 1 (K441) POSITION SIGNAL 2 CIRCUIT FOR AN OPEN/HIGH RESISTANCE**

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
    2. Measure the resistance of the CMP Sensor 1 (K441) Position Signal 2 circuit between the CMP Sensor 1 harness connector and the GPEC Adaptor.

       Is the resistance below 3.0 Ohms?

       Yes

       - Go To 12

       No

       - Repair the CMP Sensor 1 (K441) Position Signal 2 circuit for an open or high resistance.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

12. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure**

with the adaptor tool and a gauge on the later model engines where the adaptor can be used.

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

Is the oil pressure reading stable and above 16.0 psi?

Yes

- Go To 13

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 14

No

- Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK THE CAMSHAFT 1/1 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.
    2. Remove the Camshaft Position Solenoid 1/1.
    3. Inspect the spring loaded spool valve on the Oil Control Valve.

    NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

    4. Push and release the spring loaded spool valve against the return spring with a small punch.

    NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

    Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

    Yes

    - Go To 15

    No

    - Replace the Camshaft 1/1 Oil Control Valve in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

15. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
    1. Remove and exchange the CMP Sensor 1 with the CMP Sensor on the opposite bank.

    NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

    2. Reconnect the PCM C2 and Cam Sensor harness connectors.
    3. Turn the ignition on,
    4. With the scan tool, erase DTCs.
    5. Start the engine and allow it to idle or crank the engine if it will not start.
    6. With the scan tool, read DTCs.

    Did the CMP Sensor DTCs for the opposite bank set as active?

    Yes

    - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank**

Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 16

16. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    2. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Were any issues found with the CMP Sensor Tone Wheel?

    Yes

    - Replace the Camshaft Assembly in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 17
17. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 18
18. **CHECK THE CAM PHASER AND CAMSHAFT ASSEMBLY**
    1. Check the Cam Phaser to verify it has returned to lock pin.

2. Put a wrench on the flat of the Camshaft behind the phaser and attempt to move the Camshaft back and forth.

NOTE: **The Cam Phaser should always return to lock pin when the engine is turned off. If the Cam Phaser is not at lock pin, there will be movement felt between the Camshaft and the Cam Phaser.**

Is there movement between the Camshaft and Cam Phaser?

Yes

- Replace the Cam Phaser in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Go To 19

No

- Replace the Cam Phaser and Camshaft in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Go To 19

19. **VERIFY THE REPAIR**
    1. With the scan tool, erase DTCs.
    2. Test drive the vehicle in accordance with the Freeze Frame data collected.

    Did the DTC return?

    Yes

    - Go To 20

    No

    - Repair is complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

20. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.

- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 21

No

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
- Test complete.

21. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

    Did the CMP Sensor DTC return?

    Yes

    - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair is complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
22. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

   NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

   Is the oil pressure reading stable and above 16.0 psi?

   Yes

   - Go To 23

   No

   - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

23. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

    NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

    Is the oil pressure reading stable and above 14.0 psi?

    Yes

    - Go To 24

    No

    - Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or

CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

24. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 25
25. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.

9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 26

    No

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
    - Test complete.

26. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

       Did the CMP Sensor DTC return?

       Yes

       - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Repair is complete.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

27. **WIRE HARNESS/CKP SENSOR INSPECTION**
    1. Turn the ignition off.
    2. Disconnect the harness connectors at the PCM and Cam Sensor. Inspect for wire chaffing or rub conditions, spread terminals, terminals pushed out of the wiring connector, bent terminals at the PCM and Cam Sensor, water in the connector cavities, presence of corrosion on the terminals of the connectors or components.
    3. Visually inspect the mounting area of Cam Sensor for debris/damage or a loose sensor. Remove the Cam Sensor and inspect the end of the sensor for signs of damage or debris. Rotate the engine and if possible, inspect the tone wheel for any signs of damage. Reinstall the Cam Sensor and ensure that the sensor is properly installed and torqued to proper specification.

NOTE: **Due to the fact that this DTC is set by an intermittent loss of the signal, the DTC may be caused by a poor connection at the Cam Sensor or PCM terminals, or a poor signal between the Cam Sensor**

and tone wheel. Because of this, unplugging and reconnecting the harness connectors, or repositioning the Cam Sensor will often repair the condition that set the DTC.

Were any problems found?

Yes

- Perform the appropriate repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 28

28. **CHECK THE VEHICLE'S REPAIR HISTORY**
    1. Check the history of the vehicle for previous Cam Sensor related DTCs.

       Did the repair history show that the vehicle was previously in the dealership with a Cam Sensor fault?

       Yes

       - If the current DTC being diagnosed is for the **same** engine bank as the DTC that set on the previous visit, perform the diagnostics starting at test step #12 in this diagnostic procedure.
       - If the current DTC being diagnosed is for the **opposite** engine bank as the DTC that set on the previous visit, replace the Cam Sensor in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Swap the Cam Sensor with the Cam Sensor on the opposite bank and clear DTCs. The cause may have been a poor connection at one of the harness connectors. Unplugging and reconnecting the harness connector may resolve the issue. Verify the DTC does not return.

         NOTE: **The sensors must be exchanged to aid in determining the possible failure if the vehicle returns to the dealership in the future with another Cam Sensor related DTC.**

       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0369-CAMSHAFT POSITION SENSOR INTERMITTENT - BANK 1 SENSOR 2

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Camshaft Position (CMP) Sensor circuits consist of a Powertrain Control Module (PCM) supplied 5-Volt reference circuit, low reference circuit, and an output signal circuit. The CMP Sensor detects magnetic flux from the peaks and valleys between the magnets of the tone wheel attached to the camshaft. As each magnet rotates past the CMP Sensor, the resulting change in the magnetic field is used by the sensor electronics to produce a digital output pulse. The sensor returns a digital ON/OFF DC voltage pulse of varying frequency output pulses per Camshaft revolution that represent an image of the camshaft tone wheel. The frequency of the CMP Sensor output depends on the velocity of the camshaft. The PCM decodes the tooth pattern to identify camshaft position. This information is then used to sequence the ignition timing and fuel injection events for the engine. The PCM also uses CMP Sensor output information to determine the camshaft relative position to the Crankshaft, to control the CMP Actuator operation if equipped.

NOTE: **The engine may still start even if either the Crankshaft Position (CKP) Sensor or CMP fails. The PCM eventually sorts out engine position and starts the vehicle on just one of these two inputs. However, there is a slight delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and tables below indicating the CMP Sensor, Position Solenoid/Phaser and DTC orientation).

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	**CALLOUT #**	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERFORMANCE DTCS**
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

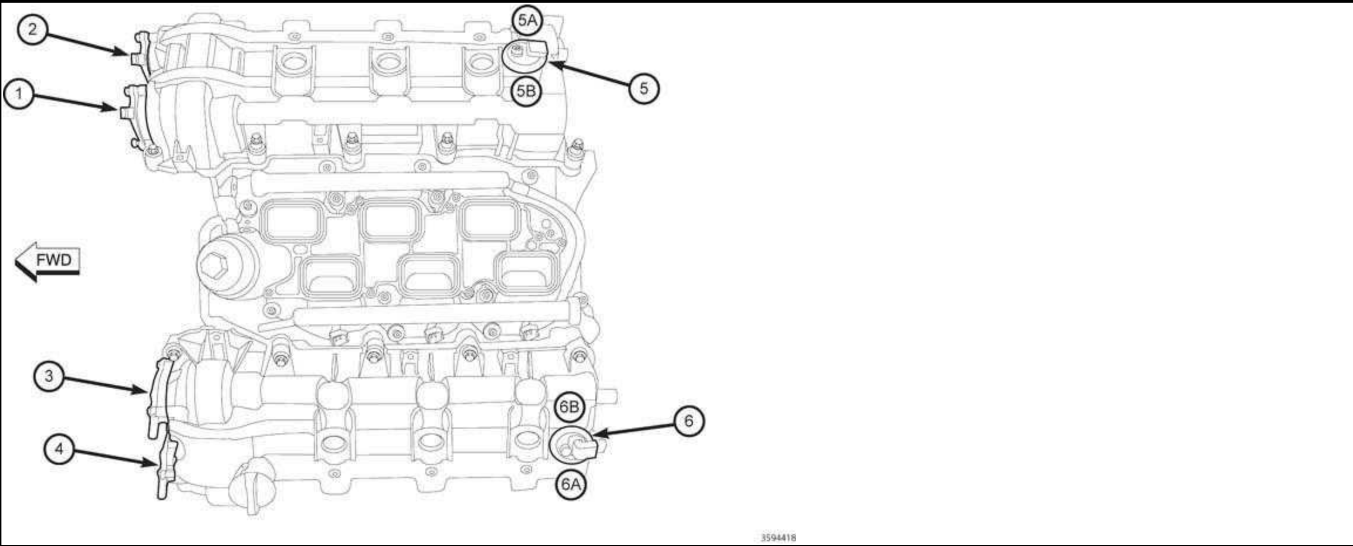
5	Bank 1 Camshaft Sensor	6B	CMP Sensor - Bank 2 Sensor 2 (INTAKE)



WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage is above approximately 11.0 volts.

SET CONDITION

- With the engine running, the Powertrain Control Module (PCM) acquires and locks in on a pattern for the Camshaft Position (CMP) Sensor signal. If the CMP Sensor signal pattern changes between unlock and lock at least four times during a period of eight Crankshaft revolutions, a fault is set.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
LOW ENGINE OIL LEVEL
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT OPEN
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
5-VOLT SUPPLY CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 1/2 SIGNAL CIRCUIT SHORTED TO VOLTAGE
CMP 1/2 SIGNAL CIRCUIT SHORTED TO GROUND
CMP 1/2 SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 1/2 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CAMSHAFT POSITION SENSOR 1
CAMSHAFT TONE WHEEL LOOSE/DAMAGED OR MISALIGNED
CAMSHAFT PHASER 1/1 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT PHASER 1/1 FAULTY OR INTERMITTENTLY BINDING/STICKING

Possible Causes
OIL PRESSURE ISSUE IN CYLINDER HEAD
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK THE ENGINE OIL LEVEL AND CONDITION**
    1. Turn the ignition off.

    NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

    - **LOW ENGINE OIL LEVEL**
    - **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL**
    - **INCORRECT ENGINE OIL VISCOSITY**
    - **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
    - **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

    Were any of the above conditions present?

    Yes

    - Repair as necessary. If the engine oil was not at the proper level, top off the engine oil to the proper specification. Start the engine and allow it to idle for 2 - 3 minutes. Turn the engine off, ignition on, and using the scan tool, erase the DTC. Start the engine and drive the vehicle to verify repair. If the DTC does not return, repair is complete.
    - If the DTC returns, Go To 3

    No

    - Go To 2
2. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on the repair order. Copy DTC and Freeze Frame information.
    3. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    4. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 3

No

- Go To 27

3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

        Are there any 5-Volt Reference, Dual Stage Oil Pump or Oil Pressure related DTCs active or pending?

        Yes

        - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

        No

        - Go To 4

4. **CHECK FOR RELATED CAM SENSOR DTCS**

    Is the P0340 or P0344 DTC also active at this time?

    Yes

    - Go To 5

    No

    - Go To 8

5. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT**

    NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

    1. Turn the ignition off.
    2. Disconnect the CMP Sensor 1 harness connector.
    3. Turn the ignition on.
    4. Measure the voltage on the (F856) 5-Volt Supply circuit at the CMP Sensor 1 harness connector.

        Is the voltage between 4.8 and 5.2 volts?

        Yes

        - Go To 6

        No

        - Repair the (F856) 5-Volt Supply circuit for an open or shorted circuit.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE CMP SENSOR 1 (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. Turn the ignition off.
    2. Disconnect the PCM C2 harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

3. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
4. Measure the resistance of the CMP Sensor 1 (K900) Sensor Ground circuit between the CMP Sensor 1 harness connector and the GPEC Adaptor.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 7

   No

   - Repair the CMP Sensor 1 (K900) Sensor Ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
   1. Remove and exchange the CMP Sensor 1 with the CMP Sensor on the opposite bank.

      NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

   2. Reconnect the PCM C2 and CMP Sensor harness connectors.
   3. Turn the ignition on,
   4. With the scan tool, erase DTCs.
   5. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.
   6. With the scan tool, read DTCs.

   Did the CMP Sensor DTCs for the opposite bank set?

   Yes

   - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 22

8. **CHECK THE CMP SENSOR 1 (K441) POSITION SIGNAL 2 CIRCUIT FOR A SHORT TO VOLTAGE**

   NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

   1. Disconnect the CMP Sensor 1 harness connector.
   2. Measure the voltage on the CMP Sensor 1 (K441) Position Signal 2 circuit in the CMP Sensor 1 harness connector.

      Is the voltage above 5.2 volts?

      Yes

      - Repair the CMP Sensor 1 (K441) Position Signal 2 circuit for a short to voltage.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 9
9. **CHECK THE CMP SENSOR 1 (K441) POSITION SIGNAL 2 CIRCUIT FOR A SHORT TO GROUND**
   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.
   3. Check for continuity between ground and the CMP Sensor 1 (K441) Position Signal 2 circuit at the CMP Sensor 1 harness connector.

      Is there continuity between ground and the CMP Sensor 1 (K441) Position Signal 2 circuit?

      Yes

      - Repair the CMP Sensor 1 (K441) Position Signal 2 circuit for a short to ground.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 10
10. **CHECK FOR THE CMP SENSOR 1 (K441) POSITION SIGNAL 2 CIRCUIT SHORTED TO THE CMP SENSOR 1 (K900) SENSOR GROUND CIRCUIT**
    1. Check for continuity between the CMP Sensor 1 (K441) Position Signal 2 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit at the CMP Sensor 1 harness connector.

       Is there continuity between ground and the CMP Sensor 1 (K441) Position Signal 2 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit?

       Yes

       - Repair the short between the CMP Sensor 1 (K441) Position Signal 2 circuit and the CMP Sensor 1 (K900) Sensor Ground circuit.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

- Go To 11

11. **CHECK THE CMP SENSOR 1 (K441) POSITION SIGNAL 2 CIRCUIT FOR AN OPEN/HIGH RESISTANCE**

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
    2. Measure the resistance of the CMP Sensor 1 (K441) Position Signal 2 circuit between the CMP Sensor 1 harness connector and the GPEC Adaptor.

       Is the resistance below 3.0 Ohms?

       Yes

       - Go To 12

       No

       - Repair the CMP Sensor 1 (K441) Position Signal 2 circuit for an open or high resistance.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

12. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

    1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
    2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
    3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
    4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
    5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

       NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

       Is the oil pressure reading stable and above 16.0 psi?

       Yes

       - Go To 13

       No

       - Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

    NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

    Is the oil pressure reading stable and above 14.0 psi?

    Yes

    - Go To 14

    No

    - Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK THE CAMSHAFT 1/1 OIL CONTROL VALVE OPERATION**
    1. Turn the ignition off.
    2. Remove the Camshaft Position Solenoid 1/1.
    3. Inspect the spring loaded spool valve on the Oil Control Valve.

    NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

    4. Push and release the spring loaded spool valve against the return spring with a small punch.

    NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

    Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

    Yes

    - Go To 15

    No

    - Replace the Camshaft 1/1 Oil Control Valve in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing

chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.

- Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

15. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
    1. Remove and exchange the CMP Sensor 1 with the CMP Sensor on the opposite bank.

       NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

    2. Reconnect the PCM C2 and Cam Sensor harness connectors.
    3. Turn the ignition on,
    4. With the scan tool, erase DTCs.
    5. Start the engine and allow it to idle or crank the engine if it will not start.
    6. With the scan tool, read DTCs.

    Did the CMP Sensor DTCs for the opposite bank set as active?

    Yes

    - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to ENGINE SENSORS, REMOVAL AND INSTALLATION . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

    No

    - Go To 16

16. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    2. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Were any issues found with the CMP Sensor Tone Wheel?

    Yes

    - Replace the Camshaft Assembly in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to POWERTRAIN VERIFICATION TEST .

No

- Go To 17

17. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 18

18. **CHECK THE CAM PHASER AND CAMSHAFT ASSEMBLY**
    1. Check the Cam Phaser to verify it has returned to lock pin.
    2. Put a wrench on the flat of the Camshaft behind the phaser and attempt to move the Camshaft back and forth.

    NOTE: **The Cam Phaser should always return to lock pin when the engine is turned off. If the Cam Phaser is not at lock pin, there will be movement felt between the Camshaft and the Cam Phaser.**

    Is there movement between the Camshaft and Cam Phaser?

    Yes

    - Replace the Cam Phaser in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Go To 19

    No

    - Replace the Cam Phaser and Camshaft in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Go To 19

19. **VERIFY THE REPAIR**
    1. With the scan tool, erase DTCs.

2. Test drive the vehicle in accordance with the Freeze Frame data collected.

   Did the DTC return?

   Yes

   - Go To 20

   No

   - Repair is complete.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

20. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
       - Proper connector installation.
       - Damaged connector locks.
       - Corrosion.
       - Other signs of water intrusion.
       - Weather seal damage (if equipped).
       - Bent terminals.
       - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
       - Terminals that have been pushed back into the connector cavity.
       - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Go To 21

        No

        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

- Test complete.

21. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

    Did the CMP Sensor DTC return?

    Yes

    - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair is complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

22. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.

    1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
    2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
    3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
    4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
    5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

       NOTE: If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.

    Is the oil pressure reading stable and above 16.0 psi?

    Yes

    - Go To 23

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

23. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

    NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

    Is the oil pressure reading stable and above 14.0 psi?

    Yes

    - Go To 24

    No

    - Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

24. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 25

25. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
        - Proper connector installation.
        - Damaged connector locks.
        - Corrosion.
        - Other signs of water intrusion.
        - Weather seal damage (if equipped).
        - Bent terminals.
        - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
        - Terminals that have been pushed back into the connector cavity.
        - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.

    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
    9. With the scan tool, erase DTCs.
    10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
    11. With the scan tool, read DTCs.

        Did the DTC return?

        Yes

        - Go To 26

        No

        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
        - Test complete.

26. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

       Did the CMP Sensor DTC return?

Yes

- Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. Refer to **CYLINDER HEAD ASSEMBLY, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Repair is complete.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

27. **WIRE HARNESS/CKP SENSOR INSPECTION**
    1. Turn the ignition off.
    2. Disconnect the harness connectors at the PCM and Cam Sensor. Inspect for wire chaffing or rub conditions, spread terminals, terminals pushed out of the wiring connector, bent terminals at the PCM and Cam Sensor, water in the connector cavities, presence of corrosion on the terminals of the connectors or components.
    3. Visually inspect the mounting area of Cam Sensor for debris/damage or a loose sensor. Remove the Cam Sensor and inspect the end of the sensor for signs of damage or debris. Rotate the engine and if possible, inspect the tone wheel for any signs of damage. Reinstall the Cam Sensor and ensure that the sensor is properly installed and torqued to proper specification.

    NOTE: **Due to the fact that this DTC is set by an intermittent loss of the signal, the DTC may be caused by a poor connection at the Cam Sensor or PCM terminals, or a poor signal between the Cam Sensor and tone wheel. Because of this, unplugging and reconnecting the harness connectors, or repositioning the Cam Sensor will often repair the condition that set the DTC.**

    Were any problems found?

    Yes

    - Perform the appropriate repair.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 28

28. **CHECK THE VEHICLE'S REPAIR HISTORY**
    1. Check the history of the vehicle for previous Cam Sensor related DTCs.

    Did the repair history show that the vehicle was previously in the dealership with a Cam Sensor fault?

    Yes

    - If the current DTC being diagnosed is for the **same** engine bank as the DTC that set on the previous visit, perform the diagnostics starting at test step #12 in this diagnostic procedure.

- If the current DTC being diagnosed is for the **opposite** engine bank as the DTC that set on the previous visit, replace the Cam Sensor in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Swap the Cam Sensor with the Cam Sensor on the opposite bank and clear DTCs. The cause may have been a poor connection at one of the harness connectors. Unplugging and reconnecting the harness connector may resolve the issue. Verify the DTC does not return.

  NOTE: **The sensors must be exchanged to aid in determining the possible failure if the vehicle returns to the dealership in the future with another Cam Sensor related DTC.**

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0390-CAMSHAFT POSITION SENSOR CIRCUIT - BANK 2 SENSOR 2

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Camshaft Position (CMP) Sensor circuits consist of a Powertrain Control Module (PCM) supplied 5-Volt reference circuit, low reference circuit, and an output signal circuit. The CMP Sensor detects magnetic flux from the peaks and valleys between the magnets of the tone wheel attached to the camshaft. As each magnet rotates past the CMP Sensor, the resulting change in the magnetic field is used by the sensor electronics to produce a digital output pulse. The sensor returns a digital ON/OFF DC voltage pulse of varying frequency output pulses per Camshaft revolution that represent an image of the camshaft tone wheel. The frequency of the CMP Sensor output depends on the velocity of the camshaft. The PCM decodes the tooth pattern to identify camshaft position. This information is then used to sequence the ignition timing and fuel injection events for the engine. The PCM also uses CMP Sensor output information to determine the camshaft relative position to the Crankshaft, to control the CMP Actuator operation if equipped.

NOTE: **The engine may still start even if either the Crankshaft Position (CKP) Sensor or CMP fails. The PCM eventually sorts out engine position and starts the vehicle on just one of these two inputs. However, there is a slight delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and tables below indicating the CMP Sensor, Position Solenoid/Phaser and DTC orientation).

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	CALLOUT #	RELATED CAM SENSOR DTCS	PHASER/ACTUATOR DTCS	MISALIGNMENT DTCS	COLD START PERFORMANCE DTCS
Bank 1 Intake Camshaft	1	P0365, P0369	P000A, P0010	P0017	P052A, P052B

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT					
CAMSHAFT LOCATIONS	**CALLOUT #**	**RELATED CAM SENSOR DTCS**	**PHASER/ACTUATOR DTCS**	**MISALIGNMENT DTCS**	**COLD START PERFORMANCE DTCS**
Bank 1 Exhaust Camshaft	2	P0340, P0344	P000B, P0013	P0016	P054A, P054B
Bank 2 Intake Camshaft	3	P0390, P0394	P000C, P0020	P0019	P052C, P052D
Bank 2 Exhaust Camshaft	4	P0345, P0349	P000D, P0023	P0018	P054C, P054D

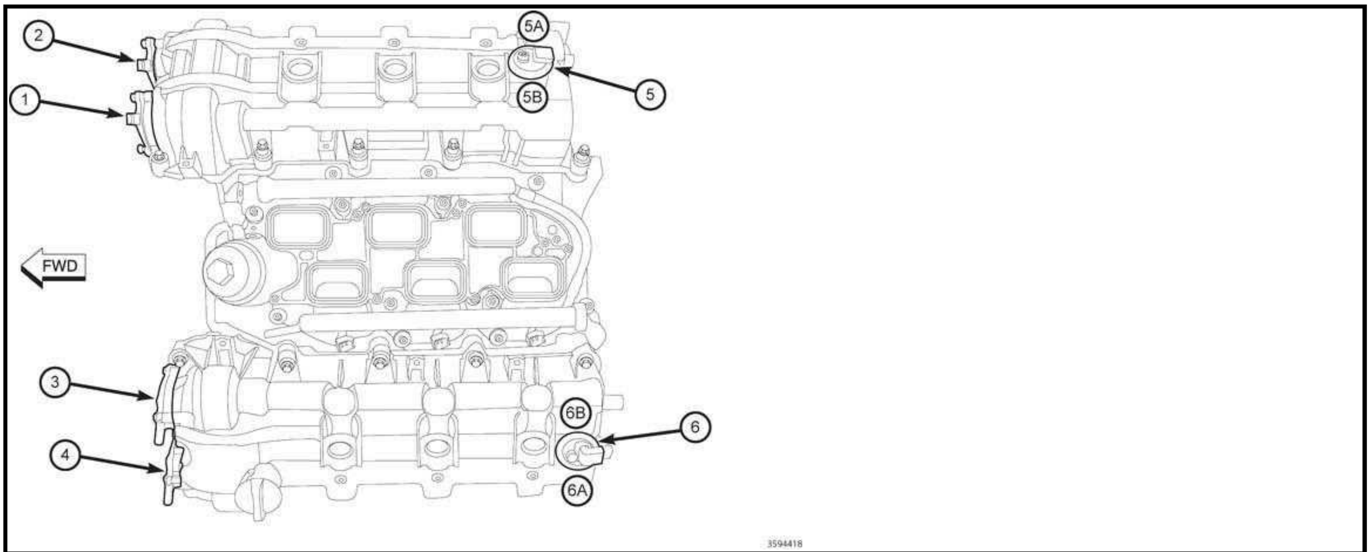
4	CMP Position Solenoid - Bank 2 Position 2 (EXHAUST)	6A	CMP Sensor - Bank 2 Sensor 1 (EXHAUST)
5	Bank 1 Camshaft Sensor	6B	CMP Sensor - Bank 2 Sensor 2 (INTAKE)



WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine cranking and with the engine running.
- Battery voltage is above approximately 11.0 volts.

SET CONDITION

- During cranking, at least 2.5 seconds have elapsed with a Crankshaft Position Sensor signal present but no Camshaft Position Sensor signal.
- With the engine running, the Camshaft Position Sensor signal is lost for at least 0.4 seconds with a Crankshaft Position Sensor signal present.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
LOW ENGINE OIL LEVEL
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT OPEN
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
5-VOLT SUPPLY CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 2/2 SIGNAL CIRCUIT SHORTED TO VOLTAGE
CMP 2/2 SIGNAL CIRCUIT SHORTED TO GROUND
CMP 2/2 SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 2/2 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CAMSHAFT POSITION SENSOR 2
CAMSHAFT TONE WHEEL LOOSE/DAMAGED OR MISALIGNED
CAMSHAFT PHASER 2/1 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT PHASER 2/1 FAULTY OR INTERMITTENTLY BINDING/STICKING
OIL PRESSURE ISSUE IN CYLINDER HEAD
POWERTRAIN CONTROL MODULE (PCM)

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK THE ENGINE OIL LEVEL AND CONDITION**
    1. Turn the ignition off.

NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

- **LOW ENGINE OIL LEVEL**
- **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL**
- **INCORRECT ENGINE OIL VISCOSITY**
- **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
- **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

Were any of the above conditions present?

Yes

- Repair as necessary. If the engine oil was not at the proper level, top off the engine oil to the proper specification. Start the engine and allow it to idle for 2 - 3 minutes. Turn the engine off, ignition on, and using the scan tool, erase the DTC. Start the engine and drive the vehicle to verify repair. If the DTC does not return, repair is complete.
- If the DTC returns, Go To 3

No

- Go To 2

2. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on the repair order. Copy DTC and Freeze Frame information.
    3. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    4. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 3

    No

    - Go To 27
3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

    Are there any 5-Volt Reference, Dual Stage Oil Pump or Oil Pressure related DTCs active or pending?

    Yes

    - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

    No

    - Go To 4
4. **CHECK FOR RELATED CAM SENSOR DTCS**

    Is the P0390 or P0394 DTC also active at this time?

    Yes

    - Go To 5

    No

    - Go To 8

5. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT**

    NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

    1. Turn the ignition off.
    2. Disconnect the CMP Sensor 2 harness connector.
    3. Turn the ignition on.
    4. Measure the voltage on the (F856) 5-Volt Supply circuit at the CMP Sensor 2 harness connector.

        Is the voltage between 4.8 and 5.2 volts?

        Yes

        - Go To 6

        No

        - Repair the (F856) 5-Volt Supply circuit for an open or shorted circuit.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
6. **CHECK THE CMP SENSOR 2 (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. Turn the ignition off.
    2. Disconnect the PCM C2 harness connector.

        CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    3. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
    4. Measure the resistance of the CMP Sensor 2 (K900) Sensor Ground circuit between the CMP Sensor 2 harness connector and the GPEC Adaptor.

        Is the resistance below 3.0 Ohms?

        Yes

        - Go To 7

        No

        - Repair the CMP Sensor 2 (K900) Sensor Ground circuit for an open or high resistance.
        - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
7. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
    1. Remove and exchange the CMP Sensor 2 with the CMP Sensor on the opposite bank.

        NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP**

Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.

2. Reconnect the PCM C2 and CMP Sensor harness connectors.
3. Turn the ignition on,
4. With the scan tool, erase DTCs.
5. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.
6. With the scan tool, read DTCs.

   Did the CMP Sensor DTCs for the opposite bank set?

   Yes

   - Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

   No

   - Go To 22

8. **CHECK THE CMP SENSOR 2 (K445) SIGNAL 2 CIRCUIT FOR A SHORT TO VOLTAGE**

   NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

   1. Disconnect the CMP Sensor 2 harness connector.
   2. Measure the voltage on the CMP Sensor 2 (K445) Signal 2 circuit in the CMP Sensor 2 harness connector.

      Is the voltage above 5.2 volts?

      Yes

      - Repair the CMP Sensor 2 (K445) Signal 2 circuit for a short to voltage.
      - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

      No

      - Go To 9

9. **CHECK THE CMP SENSOR 2 (K445) SIGNAL 2 CIRCUIT FOR A SHORT TO GROUND**
   1. Turn the ignition off.
   2. Disconnect the PCM C2 harness connector.
   3. Check for continuity between ground and the CMP Sensor 2 (K445) Signal 2 circuit at the CMP Sensor 2 harness connector.

      Is there continuity between ground and the CMP Sensor 2 (K445) Signal 2 circuit?

Yes

- Repair the CMP Sensor 2 (K445) Signal 2 circuit for a short to ground.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 10

10. **CHECK FOR THE CMP SENSOR 2 (K445) SIGNAL 2 CIRCUIT SHORTED TO THE CMP SENSOR 2 (K900) SENSOR GROUND CIRCUIT**
    1. Check for continuity between the CMP Sensor 2 (K445) Signal 2 circuit and the CMP Sensor 2 (K900) Sensor Ground circuit at the CMP Sensor 2 harness connector.

       Is there continuity between ground and the CMP Sensor 2 (K445) Signal 2 circuit and the CMP Sensor 2 (K900) Sensor Ground circuit?

       Yes

       - Repair the short between the CMP Sensor 2 (K445) Signal 2 circuit and the CMP Sensor 2 (K900) Sensor Ground circuit.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Go To 11

11. **CHECK THE CMP SENSOR 2 (K445) SIGNAL 2 CIRCUIT FOR AN OPEN/HIGH RESISTANCE**

    CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

    1. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
    2. Measure the resistance of the CMP Sensor 2 (K445) Signal 2 circuit between the CMP Sensor 2 harness connector and the GPEC Adaptor.

       Is the resistance below 3.0 Ohms?

       Yes

       - Go To 12

       No

       - Repair the CMP Sensor 2 (K445) Signal 2 circuit for an open or high resistance.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

12. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

    NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

Is the oil pressure reading stable and above 16.0 psi?

Yes

- Go To 13

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

13. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

NOTE: **The oil pressure reading at the Cylinder Head should be within above 14.0 psi.**

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 14

No

- Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

14. **CHECK THE CAMSHAFT 2/2 OIL CONTROL VALVE OPERATION**

1. Turn the ignition off.
2. Remove the Camshaft Position Solenoid 2/2.
3. Inspect the spring loaded spool valve on the Oil Control Valve.

NOTE: **The spring loaded spool valve should be flush with the surface of the Oil Control Valve when at rest.**

4. Push and release the spring loaded spool valve against the return spring with a small punch.

NOTE: **The spring loaded spool valve should move freely without binding and return to the flush position if there are no problems with the Oil Control Valve.**

Was the spring loaded spool valve flush and able to move freely without dragging or sticking?

Yes

- Go To 15

No

- Replace the Camshaft 2/2 Oil Control Valve in accordance with the Service Information. Refer to **PHASER, CAMSHAFT, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

15. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
    1. Remove and exchange the CMP Sensor 2 with the CMP Sensor on the opposite bank.

NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

2. Reconnect the PCM C2 and Cam Sensor harness connectors.
3. Turn the ignition on,
4. With the scan tool, erase DTCs.
5. Start the engine and allow it to idle or crank the engine if it will not start.
6. With the scan tool, read DTCs.

Did the CMP Sensor DTCs for the opposite bank set as active?

Yes

- Replace the faulty Camshaft Position Sensor in accordance with the Service Information. Refer to **ENGINE SENSORS, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears.

Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 16

16. **INSPECT CAMSHAFT SENSOR TONE WHEEL FOR DAMAGE OR LOOSENESS**
    1. Remove the Cylinder Head Cover and inspect the Camshaft Sensor Tone Wheel for any looseness or signs of damage.
    2. Using the (special tool #2027902090, Check Tool, Tone Wheel Right) check the alignment of the CMP Sensor Tone Wheel in accordance with the service information.

    Were any issues found with the CMP Sensor Tone Wheel?

    Yes

    - Replace the Camshaft Assembly in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 17

17. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 18

18. **CHECK THE CAM PHASER AND CAMSHAFT ASSEMBLY**
    1. Check the Cam Phaser to verify it has returned to lock pin.

2. Put a wrench on the flat of the Camshaft behind the phaser and attempt to move the Camshaft back and forth.

   NOTE: **The Cam Phaser should always return to lock pin when the engine is turned off. If the Cam Phaser is not at lock pin, there will be movement felt between the Camshaft and the Cam Phaser.**

   Is there movement between the Camshaft and Cam Phaser?

   Yes

   - Replace the Cam Phaser in accordance with the Service Information. . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Go To 19

   No

   - Replace the Cam Phaser and Camshaft in accordance with the Service Information. Refer to **CAMSHAFT, ENGINE, REMOVAL AND INSTALLATION** . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
   - Go To 19

19. **VERIFY THE REPAIR**
    1. With the scan tool, erase DTCs.
    2. Test drive the vehicle in accordance with the Freeze Frame data collected.

    Did the DTC return?

    Yes

    - Go To 20

    No

    - Repair is complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

20. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
       - Proper connector installation.
       - Damaged connector locks.
       - Corrosion.
       - Other signs of water intrusion.
       - Weather seal damage (if equipped).

- Bent terminals.
- Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
- Terminals that have been pushed back into the connector cavity.
- Check for spread terminals and verify proper terminal tension.

Repair any conditions that are found.

6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.
9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

Did the DTC return?

Yes

- Go To 21

No

- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
- Test complete.

21. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

    Did the CMP Sensor DTC return?

    Yes

    - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Repair is complete.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
22. **CHECK THE ENGINE OIL PRESSURE AND ENGINE MECHANICAL CONDITION**

NOTE: **During this test step it will be easier to check the oil pressure reading with the scan tool, especially during the test drive. If the oil pressure reading is borderline on the scan tool or suspected to be off, verify the oil pressure with the adaptor tool and a gauge on the later model engines where the adaptor can be used.**

1. Start the engine and allow it to reach operating temperature. Check the oil pressure at idle and while test driving the vehicle in accordance with the Freeze Frame data collected.
2. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.
3. To check the oil pressure manually, turn the engine off. Remove the Oil Filter cap.
4. Install the (special tool #2021500090, Adapter, Late Version 3.6L Oil Pressure Test)to the oil filter cap and install an oil pressure gauge to the adaptor. If the adaptor is not available, monitor the oil pressure reading with the scan tool.
5. Start the engine and allow it to reach operating temperature. Monitor the engine oil pressure reading on the gauge while operating the vehicle.

NOTE: **If the oil pressure goes below 16.0 psi or is oscillating excessively, it can cause a delay in Cam Phaser movement sufficient enough to set a slow response or CMP Sensor intermittent DTC.**

Is the oil pressure reading stable and above 16.0 psi?

Yes

- Go To 23

No

- Repair the engine oiling or mechanical condition (i.e. improper oil drain back, oil sludge, damaged oil pump, pick-up tube or seal, etc.).
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

23. **CHECK THE ENGINE OIL PRESSURE AT THE CYLINDER HEAD**
    1. Remove the front Variable Valve Lift (VVL) Solenoid from the Cylinder Head.
    2. Install the (special tool #2027300090, Kit, VVL Adapters) in place of the solenoid.
    3. Start the engine and allow it to idle.
    4. Monitor the engine oil pressure reading on the scan tool while operating the vehicle.

NOTE: **The oil pressure reading at the Cylinder Head should be above 14.0 psi.**

Is the oil pressure reading stable and above 14.0 psi?

Yes

- Go To 24

No

- Remove the Cylinder Head Cover and visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head and repair as necessary. Verify that the oil galley plugs are torqued to the proper specification. If the oil galley plugs/screws are torqued properly and don't appear leaking, replace the Cylinder Head in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or

CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" procedure.
  - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

24. **INSPECT THE CYLINDER HEAD FOR MISSING OR IMPROPERLY TORQUED OIL GALLEY PLUGS, AND FOR ANY DAMAGE TO THE TIMING CHAIN LINKS OF PINS**
    1. Visually inspect the Cylinder Head for any missing or damaged plugs/screws in the oil galleys near the front of the Cylinder Head.
    2. Verify that the oil galley plugs are torqued to the proper specification.
    3. Visually inspect the timing chain for broken links or damaged chain pins. Check the Timing Chain tensioners for proper operation.

    Were any issues found with the oil galley plugs or timing chain links, pins or tensioners?

    Yes

    - Perform the appropriate repair. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Go To 25
25. **CHECK RELATED PCM AND COMPONENT CONNECTIONS**
    1. Perform any Service Bulletins that apply.
    2. Disconnect all PCM harness connectors.
    3. Disconnect all related in-line harness connections (if equipped).
    4. Disconnect the related component harness connectors.
    5. Inspect harness connectors, component connectors, and all male and female terminals for the following conditions:
       - Proper connector installation.
       - Damaged connector locks.
       - Corrosion.
       - Other signs of water intrusion.
       - Weather seal damage (if equipped).
       - Bent terminals.
       - Overheating due to a poor connection (terminal may be discolored due to excessive current draw).
       - Terminals that have been pushed back into the connector cavity.
       - Check for spread terminals and verify proper terminal tension.

       Repair any conditions that are found.
    6. Reconnect all PCM harness connectors. Be certain that all harness connectors are fully seated and the connector locks are fully engaged.
    7. Reconnect all in-line harness connectors (if equipped). Be certain that all connectors are fully seated and the connector locks are fully engaged.
    8. Reconnect all related component harness connectors. Be certain that all connectors are fully seated and the connector locks are fully engaged.

9. With the scan tool, erase DTCs.
10. Test drive or operate the vehicle in accordance with the when monitored and set conditions.
11. With the scan tool, read DTCs.

    Did the DTC return?

    Yes

    - Go To 26

    No

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .
    - Test complete.

26. **REPLACE THE PCM AND RETEST FOR DTC**
    1. Replace the Powertrain Control Module in accordance with the Service information. Refer to **MODULE, POWERTRAIN CONTROL (PCM), REMOVAL AND INSTALLATION** .
    2. Turn the ignition on.
    3. With the scan tool, erase DTCs.
    4. Start the engine and allow it to idle.
    5. With the scan tool, read DTCs.

       Did the CMP Sensor DTC return?

       Yes

       - Replace the Cylinder Head Assembly, Timing Chain and tensioners in accordance with the Service Information. . **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, Timing Chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

       No

       - Repair is complete.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

27. **WIRE HARNESS/CKP SENSOR INSPECTION**
    1. Turn the ignition off.
    2. Disconnect the harness connectors at the PCM and Cam Sensor. Inspect for wire chaffing or rub conditions, spread terminals, terminals pushed out of the wiring connector, bent terminals at the PCM and Cam Sensor, water in the connector cavities, presence of corrosion on the terminals of the connectors or components.
    3. Visually inspect the mounting area of Cam Sensor for debris/damage or a loose sensor. Remove the Cam Sensor and inspect the end of the sensor for signs of damage or debris. Rotate the engine and if possible, inspect the tone wheel for any signs of damage. Reinstall the Cam Sensor and ensure that the sensor is properly installed and torqued to proper specification.

       NOTE: **Due to the fact that this DTC is set by an intermittent loss of the signal, the DTC may be caused by a poor connection at the Cam Sensor or PCM terminals, or a poor signal between the Cam Sensor and tone wheel. Because of this, unplugging and reconnecting the**

harness connectors, or repositioning the Cam Sensor will often repair the condition that set the DTC.

Were any problems found?

Yes

- Perform the appropriate repair.
- Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

No

- Go To 28

28. **CHECK THE VEHICLE'S REPAIR HISTORY**
    1. Check the history of the vehicle for previous Cam Sensor related DTCs.

    Did the repair history show that the vehicle was previously in the dealership with a Cam Sensor fault?

    Yes

    - If the current DTC being diagnosed is for the **same** engine bank as the DTC that set on the previous visit, perform the diagnostics starting at test step #12 in this diagnostic procedure.
    - If the current DTC being diagnosed is for the **opposite** engine bank as the DTC that set on the previous visit, replace the Cam Sensor in accordance with the Service Information. **The "Cam/Crank Relearn" Procedure** must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.
    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

    No

    - Swap the Cam Sensor with the Cam Sensor on the opposite bank and clear DTCs. The cause may have been a poor connection at one of the harness connectors. Unplugging and reconnecting the harness connector may resolve the issue. Verify the DTC does not return.

    NOTE: **The sensors must be exchanged to aid in determining the possible failure if the vehicle returns to the dealership in the future with another Cam Sensor related DTC.**

    - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

P0394-CAMSHAFT POSITION SENSOR INTERMITTENT - BANK 2 SENSOR 2

For a complete IGNITION SYSTEM wiring diagram, **refer to the appropriate wiring information** .

THEORY OF OPERATION

The Camshaft Position (CMP) Sensor circuits consist of a Powertrain Control Module (PCM) supplied 5-Volt reference circuit, low reference circuit, and an output signal circuit. The CMP Sensor detects magnetic flux from the peaks and valleys between the magnets of the tone wheel attached to the camshaft. As each magnet rotates past the CMP Sensor, the resulting change in the magnetic field is used by the sensor electronics to produce a digital output pulse. The sensor returns a digital ON/OFF DC voltage pulse of varying frequency output pulses per Camshaft revolution that represent an image of the camshaft tone wheel. The frequency of the

CMP Sensor output depends on the velocity of the camshaft. The PCM decodes the tooth pattern to identify camshaft position. This information is then used to sequence the ignition timing and fuel injection events for the engine. The PCM also uses CMP Sensor output information to determine the camshaft relative position to the Crankshaft, to control the CMP Actuator operation if equipped.

NOTE: **The engine may still start even if either the Crankshaft Position (CKP) Sensor or CMP fails. The PCM eventually sorts out engine position and starts the vehicle on just one of these two inputs. However, there is a slight delay in starting until the PCM can establish sync. A DTC is set and the MIL illuminates if either of the CKP or CMP Sensor signals are not present during engine cranking.**

There are four Camshafts and two CMP Sensors. Each CMP Sensor has two CMP Sensor signals that provide feedback indicating the position of each Camshaft on its correlating engine bank (See the illustration and tables below indicating the CMP Sensor, Position Solenoid/Phaser and DTC orientation).

3.2L / 3.6L DTCs RELATED TO EACH CAMSHAFT

WHEN MONITORED

This diagnostic runs continuously when the following conditions are met:

- With the engine running.
- Battery voltage is above approximately 11.0 volts.

SET CONDITION

- With the engine running, the Powertrain Control Module (PCM) acquires and locks in on a pattern for the Camshaft Position (CMP) Sensor signal. If the CMP Sensor signal pattern changes between unlock and lock at least four times during a period of eight Crankshaft revolutions, a fault is set.

DEFAULT ACTION

- The MIL will illuminate.
- If the vehicle is equipped with the stop/start feature, the system will be disabled when this DTC is active.

POSSIBLE CAUSES

Possible Causes
LOW ENGINE OIL LEVEL
ENGINE OIL AERATED OR CONTAMINATED
INCORRECT ENGINE OIL FILTER
INSUFFICIENT OIL PRESSURE DUE TO A MECHANICAL FAILURE IN THE OILING SYSTEM
5-VOLT SUPPLY CIRCUIT SHORTED TO VOLTAGE
5-VOLT SUPPLY CIRCUIT OPEN
5-VOLT SUPPLY CIRCUIT SHORTED TO GROUND
5-VOLT SUPPLY CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 2/2 SIGNAL CIRCUIT SHORTED TO VOLTAGE
CMP 2/2 SIGNAL CIRCUIT SHORTED TO GROUND
CMP 2/2 SIGNAL CIRCUIT SHORTED TO THE SENSOR GROUND CIRCUIT
CMP 2/2 SIGNAL CIRCUIT OPEN/HIGH RESISTANCE
SENSOR GROUND CIRCUIT OPEN/HIGH RESISTANCE
CAMSHAFT POSITION SENSOR 2
CAMSHAFT TONE WHEEL LOOSE/DAMAGED OR MISALIGNED
CAMSHAFT PHASER 2/1 OIL CONTROL VALVE FAULTY OR INTERMITTENTLY BINDING/STICKING SPOOL VALVE
CAMSHAFT PHASER 2/1 FAULTY OR INTERMITTENTLY BINDING/STICKING

Possible Causes
POWERTRAIN CONTROL MODULE (PCM)
OIL PRESSURE ISSUE IN CYLINDER HEAD

Always perform the PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE before proceeding. Refer to PRE-DIAGNOSTIC TROUBLESHOOTING PROCEDURE .

DIAGNOSTIC TEST

1. **CHECK THE ENGINE OIL LEVEL AND CONDITION**
    1. Turn the ignition off.

    NOTE: **The following items should be checked before continuing with this procedure. Failure to do so may lead to misdiagnosis.**

    - **LOW ENGINE OIL LEVEL**
    - **CONTAMINATED, DIRTY, AERATED OR DETERIORATED ENGINE OIL**
    - **INCORRECT ENGINE OIL VISCOSITY**
    - **ENGINE OIL PRESSURE OUT OF SPECIFICATION**
    - **INCORRECT ENGINE OIL FILTER (DOES NOT MEET OEM SPECIFICATIONS)**

    Were any of the above conditions present?

    Yes

    - Repair as necessary. If the engine oil was not at the proper level, top off the engine oil to the proper specification. Start the engine and allow it to idle for 2 - 3 minutes. Turn the engine off, ignition on, and using the scan tool, erase the DTC. Start the engine and drive the vehicle to verify repair. If the DTC does not return, repair is complete.
    - If the DTC returns, Go To 3

    No

    - Go To 2
2. **CHECK FOR AN ACTIVE DTC**
    1. Turn the ignition on.
    2. With the scan tool, read DTCs and record on the repair order. Copy DTC and Freeze Frame information.
    3. Start the engine and allow it to idle or crank the engine if it will not start. Attempt to operate vehicle under conditions similar to freeze frame data.

    WARNING: **When the engine is operating, do not stand in direct line with the fan. Do not put your hands near the pulleys, belts or fan. Do not wear loose clothing. Failure to follow these instructions may result in possible serious or fatal injury.**

    4. With the scan tool, read DTCs.

    Is the DTC active or pending?

    Yes

    - Go To 3

No

- Go To 27

3. **CHECK FOR OTHER DTCS**
    1. Refer to the recorded DTCs.

       Are there any 5-Volt Reference, Dual Stage Oil Pump or Oil Pressure related DTCs active or pending?

       Yes

       - Perform the applicable diagnostic procedure(s) before continuing with this test procedure. Refer to **3.6L (GPEC 5) - DIAGNOSTIC CODE INDEX** .

       No

       - Go To 4

4. **CHECK FOR RELATED CAM SENSOR DTCS**

   Is the P0390 or P0394 DTC also active at this time?

   Yes

   - Go To 5

   No

   - Go To 8

5. **CHECK THE (F856) 5-VOLT SUPPLY CIRCUIT**

   NOTE: **Keep in mind during the following electrical circuit checks that this is an intermittent loss of the Cam Sensor signal. It may be best to wiggle the wiring harness and connectors while performing the check of the circuits.**

    1. Turn the ignition off.
    2. Disconnect the CMP Sensor 2 harness connector.
    3. Turn the ignition on.
    4. Measure the voltage on the (F856) 5-Volt Supply circuit at the CMP Sensor 2 harness connector.

       Is the voltage between 4.8 and 5.2 volts?

       Yes

       - Go To 6

       No

       - Repair the (F856) 5-Volt Supply circuit for an open or shorted circuit.
       - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

6. **CHECK THE CMP SENSOR 2 (K900) SENSOR GROUND CIRCUIT FOR AN OPEN/HIGH RESISTANCE**
    1. Turn the ignition off.
    2. Disconnect the PCM C2 harness connector.

CAUTION: **Do not probe the PCM harness connectors. Probing the PCM harness connectors will damage the PCM terminals resulting in poor terminal to pin connection. Install the GPEC Diagnostic Adaptor to perform the diagnosis.**

3. Connect the (special tool #10436, Adapter, GPEC Diagnostic).
4. Measure the resistance of the CMP Sensor 2 (K900) Sensor Ground circuit between the CMP Sensor 2 harness connector and the GPEC Adaptor.

   Is the resistance below 3.0 Ohms?

   Yes

   - Go To 7

   No

   - Repair the CMP Sensor 2 (K900) Sensor Ground circuit for an open or high resistance.
   - Perform the POWERTRAIN VERIFICATION TEST. Refer to **POWERTRAIN VERIFICATION TEST** .

7. **EXCHANGE THE CMP SENSORS AND CHECK FOR THE DTC TO CHANGE TO THE OTHER BANK**
   1. Remove and exchange the CMP Sensor 2 with the CMP Sensor on the opposite bank.

      NOTE: **Inspect the Camshaft magnetic tone wheel for damage in accordance with the Service Information. If a problem is found repair as necessary. The "Cam/Crank Relearn" Procedure must be performed every time there has been a repair/replacement made to a CMP Sensor and/or CKP Sensor, flywheel, valvetrain, timing chain or gears. Failure to do so can cause a misfire fault to set. With the scan tool, perform the "Cam/Crank Relearn" Procedure.**

   2. Reconnect the PCM C2 and CMP Sensor harness connectors.
   3. Turn the ignition on,
